The big liberator. is here!

A revolution in tissue culture techniques
by Boehringer Mannheim!

The neutral protease "Dispase" is the most favourable enzyme in tissue culture techniques for the enzymatic disintegration of tissues into single cells or to keep cells in suspension culture.

The advantages over trypsin are:

- | | |
|---|--|
| * no damage of cell membranes | * increase of the yield of living cells |
| * no inhibition of cell growth | * no loss in enzyme activity under tissue culture conditions |
| * tissue disintegration in presence of a complete nutrient medium even with serum | * no contamination by viruses or mycoplasmas possible |

Commercially available: Dispase, Grade I, Cat. No. 241 750
Dispase, Grade II, Cat. No. 165 859
Dispase/Collagenase mixture, Cat. No. 269 638

For details and working instructions please ask your local representative or:

An unconventional balance with an extra measure of accuracy

~~R503~~ RP404

Mettler DeltaRange breaks through the boundaries that used to restrict the capacity/accuracy ratios of conventional weighing instruments. And Mettler PC electronic top-loading balances are equipped with this new *Mettler DeltaRange* feature.

Just press the control bar of the Mettler PC4400, for example, and you get a 400 g fine range with readings that are 10 times as accurate as those in the coarse range. And you can do it as often as you wish, at any point of the entire weighing range. That is to say, whenever and wherever a 0.01 g readability is needed. On a balance that has a capacity of no less than 4000 g!

In practice, this means that you can use a heavy container to accurately weigh in as many components as you want. Or that you can weigh one time on a lightweight paper, the next time into a heavy recipient; both times with results that are readable to the second decimal place.

To learn more about the many things your Mettler PC balance can do for you with outstanding speed and precision, send for our detailed brochure. It's an eye-opener.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures.

Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely.

Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976).

New ¹⁴C- proteins

**The Radiochemical Centre
Amersham**

Circle No. 06 on Reader Enquiry Card.

¹⁴C-Protein molecular weight markers

Labelled proteins of known molecular weight for use as markers in gel electrophoresis are available from TRC NOW

[¹⁴C]Methylated

Lysozyme	CFA.605	MW 14,300
Carbonic anhydrase	CFA.622	MW 30,000
Ovalbumin	CFA.623	MW 46,000
Bovine serum albumin	CFA.621	MW 69,000
Phosphorylase b	CFA.609	MW 92,500
Myosin	CFA.625	MW 200,000

Specific activity 3–30 μ Ci/mg of protein

Also available

[¹⁴C]Methylated
protein mixture CFA.626

Contains equal activities of each of the 6 markers

Listing the year's papers by both author and subject, they assist quick, easy reference to past issues.

BINDERS

Keep your copies of *Nature* protected in durable black PVC binders:

- 20 plastic retention strips mean no loose parts, wire, or complex loading systems
- title blocked in gold on spine
- panel on spine for your own references

Each binder is designed to take two volumes of *Nature*; three binders will serve for a year.

Prices (including postage): UK £3.00 each, three for £8.00; Rest of World US \$6.00, three for US \$16.00.

To order, please send details and correct remittance to:

1 March 1979

Science to grow again?

WHAT is the minimum rate at which expenditure by research councils should grow in real terms in the next few years to sustain the vigour of the scientific community in Britain? A difficult question, and in some ways a meaningless one. One single aggregated figure for growth would have to cover a wide range of activities from research of great timeliness through to research that might just as well be terminated right now; it would also have to make allowance for discoveries yet to be made but which will call for the commitment of new resources in years ahead. The Advisory Board for the Research Councils (ABRC), however, make a guess at a figure in their just-issued report for the years 1976–78 (HMSO; 70p): 4%. The report gives a valuable survey of past fluctuations in financial support, from the remarkable days of 13% real growth in 1966, through the period of at-best no growth, at-worst cuts of a few per cent in the mid-1970s to the slightly calmer waters of about 1% annual growth promised for the next three years.

What lessons have been learnt from this period? That salaries drift upwards in real terms by up to one per cent each year simply because of increased seniority; that the cost of equipment drifts up also, especially now that much which was bought during the growth period of the 1960s is obsolescent—excepting that computers are still getting cheaper; that without a little financial elbow-room all money gets locked into continuing projects, buildings and staff, and new initiatives never get the start they need; that if too much growth is pumped into the system too quickly, the money injected either cannot be spent and is returned to the Treasury, or is spent hastily and not necessarily wisely. From all these considerations, the figure of 4% looks realistic. Whether it will sell in Cabinet in inflationary times, or with a possible change of government is another matter.

But whilst research done through research councils has been subject to severe restraints these past few years, and whilst the other arm of the 'dual-support system'—financial assistance for universities through the University Grants Committee (UGC)—has, if anything, experienced even greater difficulties in making ends meet, defence research and development has shown relative resilience. The ABRC reports valuably bring together the nation's R & D expenditure in one table. In

1969/70 total government R & D cost £604 million; it now (1978/9) costs £1,735 million. The proportion of this sum which has been spent on defence R & D has risen from 40% in 1969/70 to 50.5% in the current financial year.

It might be argued that during a period in which the government pared down on major civil commitments such as its contribution to the European Launcher Development Organisation, and research on Concorde, it would be natural for defence R & D to seem to grow in significance. One way to test this would be to see whether money for research councils and for the research side of University Grants Committee (UGC) support (which can only be an estimate) has kept pace with defence R & D funding. The calculation is somewhat complicated by the redistribution of funds during the Rothschild re-organisation, so we do it for the Science Research Council only, this council not having had to transfer any of its funds over the past several years to customer departments. The ratio of defence R & D expenditure to SRC plus UGC research funds was 2.55 in 1969/70, dipped as low as 2.39 in 1974/5, but now stands at 2.93. The conclusion is inevitably that defence R & D has not in recent years experienced quite the privations that much of civil science has had to undergo.

Is it right that half of all government expenditure on R & D should go to defence? No-one (as far as we know) sits in Whitehall and preordains percentages that would be appropriate for research in different areas—relative movements are therefore much more likely to reflect changing conditions within individual ministries than any clear-cut policy decision. Nevertheless the remorseless upward trend in importance of the defence R & D figure should not go unremarked. It is next to impossible to tell whether the £875 million spent this year gives value for money, but anecdotal evidence—what little there is—suggests that areas of real excellence in defence R & D establishments are few and far between, and that the general level of competence and drive is not high. Mechanisms for weeding out inferior quality in civil science by peer review are by no means perfect, but at least they exist. Do we know that within a closed organisation, whose employees possess excellent job security, adequate steps are taken to protect the taxpayer's interest? □

Environmentalists fight use of 'untested' pesticide

The EPA has been accused of playing politics over Mississippi's fire ant 'emergency'. Clive Cookson reports

ENVIRONMENTALISTS are fighting tenaciously to prevent the use in the southern United States of an untested and allegedly carcinogenic pesticide. They say the Environmental Protection Agency approved the pesticide for political reasons and against the advice of its own scientists.

Twice last year the EPA agreed to requests by the state of Mississippi to use Ferriamicide, a new organochlorine insecticide, as an emergency weapon against fire ants. Each time the Environmental Defense Fund persuaded a federal court to delay the EPA approval. Last month the EPA announced a third time that it would permit Mississippi to apply Ferriamicide to a limited area this spring. But within a fortnight the EDF persuaded the agency to delay the approval again—this time without court action—by drawing its attention to some Canadian research results.

Ferriamicide, developed by Mississippi in a state-owned chemical plant, is a combination of Mirex*, imported from Brazil, with an amine and ferrous chloride to speed up its photodecomposition in the environment. But, according to a recent report by Dr David Villeneuve, head of the Environmental contaminants section of Health and Welfare Canada (HWC), one of Ferriamicide's main decomposition products, is photo-Mirex, which is even more toxic than Mirex, the active ingredient of Ferriamicide. Pure Mirex was the chief insecticide used against fire ants until the EPA banned it in 1976 after studies indicated that it causes cancer, birth defects, and other toxic effects in mammals.

EDF general counsel William Butler says the Canadian study was widely known before the EPA's most recent approval of Ferriamicide—Dr Villeneuve presented his work at several scientific meetings—but the EPA was apparently not aware of it.

According to the EDF, the agency's whole attitude to Ferriamicide has been influenced by the desire of senior EPA administrators to appease the powerful southern politicians who have been pressing very hard for its approval. Fire ants were accidentally introduced from South America in the 1920s and have spread remorselessly across the South, biting humans and animals and impeding agriculture with their mounds. Controlling the ants has become a big political issue in the nine southern states now infested.

Almost every southern senator and

congressman, as well as state and local politicians, joined the campaign to win EPA approval for Ferriamicide. A public relations drive led by Jim Buck Ross, Mississippi's Agriculture Commissioner, persuaded 20,000 people from the state to write to the agency in support of Ferriamicide.

EPA files, which the Environmental Defense Fund obtained during last year's litigation, show that the agency was highly sensitive to this political pressure, though EPA officials insist that the decisions to approve Ferriamicide were not influenced by political considerations. Barbara Blum, EPA deputy administrator wrote on one internal note. "If it's a political decision we want to make the most of it." She was apparently referring to the opportunity to win more favourable treatment for the EPA and for the Administration's pesticides legislation in Congress—the Senate and House committees which oversee the agency and fix its budget have many prominent members from the South.

None of the scientific branches of the EPA pesticides registration division supported their senior administrators' decisions on Ferriamicide. Some, including the chemistry and fish and wildlife branches, actively opposed them. Nevertheless, Dr Blum ruled that the fire ant "emergency" justified Mississippi's use of its unlicensed and virtually untested pesticide, though she did impose more stringent safeguards than the state proposed. (The eight other infested states lodged similar requests to apply Ferriamicide over a total of 17 million acres, but the EPA has not yet ruled on their cases.)

Dr Blum accepted Mississippi's argument that there is no effective alternative treatment for large, heavily infested areas, although one or two US chemical firms are reported to be developing new ant-killers which may be available soon. The environment-

alists argue, with the support of some agricultural scientists, that Mirex itself has not halted the spread of fire ants; the area infested has increased from 30 million acres in 1962, when Mirex was first used, to 190 million acres in the late 1970s.

According to William Butler of the EDF, the only result of Mississippi's highly visible war on the ants—involving helicopters and converted B17 aircraft—has been political. Voters can see and hear that the state and federal governments are doing something about the insects which are making their lives miserable. Mr Butler likes to compare the psychology behind the war—and its practical results—with the US attempts to bomb the Vietnamese into submission.

The uncomfortable position of the EPA—under fire from the environmentalists on one side and from the politicians and farmers on the other—became more embarrassing when the head of the US Government's other major regulatory agency for toxic chemicals, the Occupational Safety and Health Administration, criticised the latest EPA authorisation of Ferriamicide in Mississippi. What Eula Bingham, Assistant Secretary of Labour responsible for safety and health, objected to was a condition imposed by the EPA that no women of child-bearing age should handle Ferriamicide. OSHA officials are said to fear that this sex bias may be used or quoted as a precedent by chemical firms wishing to exclude women from their work forces.

They also doubt whether the ban on women handling the pesticide makes any sense. Research has indicated that Mirex damages the testes of male rats and may therefore cause fathers to pass on birth defects to their children. Logically, then, only the elderly and sterile should be allowed to use it.

**Chemically Mirex is dodecachlorooctahydro - 1,3,4-methano-2H - cyclobuta-(CD) pentalene. Photo-Mirex is 8-monohydro-Mirex.*

UK union attacks GMAG bureaucracy

THE Association of University Teachers (AUT) in the UK is worried about the paperwork its members could face if the Genetic Manipulation Advisory Group's (GMAG) plans to include self-cloning experiments within its remit (see below) are adopted. Three AUT representatives expressed their concern to members of parliament last week when they gave evidence to the House of Commons Select Committee on Science and Technology which is currently examining genetic engineering.

Dr David Sherratt of Sussex University, one of the AUT representatives, explained to *Nature* after the meeting that most of the concern centres on the interpretation of part of the document published in *Nature* last year (9 November, page 104) on proposed new guidelines for the UK. The document states that laboratories intending to do self-cloning experiments should provide "a block notification" of the experiments to be done over a year, an undertaking to work in category 1* and a retrospective "detailed log of all experiments carried out".

The latter point causes Dr Sherratt most concern. "In our laboratory", he says "12-15 of us are using these techniques (cloning *E. coli* genes into *E. coli* organisms) every day." Providing GMAG with a detailed log of all such experiments (up to 1,000 in a year) could make the amount of bureaucracy the laboratory has to deal with "absolutely enormous", he claims. As yet, however, no-one knows whether a single sentence on each experiment will satisfy GMAG or whether it will require short papers. "It all depends on what they want", says Dr Sherratt.

Under the Williams guidelines, which still operate, his laboratory, together with most others, does not at the moment notify GMAG of self-cloning

experiments. Scientists have generally interpreted GMAG's definition of genetic manipulation as excluding self-cloning. During 1978, however, the Medical Research Council (MRC) indicated that self-cloning experiments should be considered by GMAG. It suddenly started to make the award of some grants for work involving self-cloning experiments conditional on those experiments being notified to GMAG. GMAG went along with this. Prior to 1978, it would seem that the MRC and GMAG had agreed with scientists that these experiments did not count as genetic manipulation.

The trouble is that GMAG's definition of genetic manipulation is ambiguous with regard to self-cloning, so it could be argued that both the MRC's interpretation and that of the scientists are correct. Even GMAG admits that it is ambiguous. Its remit is defined as: "the formation of new combinations of heritable material by the insertion of nucleic acid molecules produced, by whatever means, outside the cell, into any virus, bacterial plasmid or other vector system so as to allow their incorporation into a host organism in which they do not naturally occur but in which they are capable of continued propagation". The chief difficulty, says Dr Sherratt, arises in the meaning assigned to "they" in the phrase "in which they do not naturally occur". If it refers to the "new combinations", then all self-cloning experiments are included in the guidelines. If, on the other hand, it refers to the "nucleic acid molecules", as most scientists have assumed it does, then all self-cloning experiments are exempt from regulation. This is the point that GMAG has recently been debating.

Judy Redfearn

GMAG wants self-cloning notification

IN a controversial decision last week, Britain's Genetic Manipulation Advisory Group (GMAG) has opted to include self-cloning in its definition of "genetic manipulation", but to slacken its notification procedures for such experiments. However GMAG has not yet issued a formal statement of its new views, and will not do so until after 16 March, when it meets to decide a final form of words.

That meeting will require decisions on three crucial issues: first, what containment conditions will be required for self-cloning (and related experiments); second, what experiments to include in this slackened category; and third, what notification procedures to demand.

At present, GMAG feels that "good microbiological practice" will be sufficient, somewhat more relaxed than the present Category 1; that three or four systems could be included, such as *E. coli* in *E. coli*, and experiments likely to be undertaken in teaching; and that the notification should be more of a formality than a chore. But precisely where the group stands on these matters is not decided.

For comparison the revised guidelines of the US National Institutes of Health clearly exempt from any control all self-cloning experiments, experiments involving donor-host pairs that naturally exchange DNA, and some cloning experiments with viral DNA in viral vectors.

Britain snowed up, January 1979

World climate conference turns to the weather

IT is the short term variability of climate—to most people, year-to-year variation in 'the weather'—that matters most, not the longer term 'climatic' variation with which some (perhaps especially some of the environmentalists) are more deeply concerned. This is a first conclusion to be drawn from the "Conference of Experts on Climate and Mankind" convened recently in Geneva by the World Meteorological Organisation.

Certainly, the effects of short-term variability are serious enough. It was one such phenomenon, the Sahel drought of 1968-73, which in fact brought the need for some sort of climate conference to the fore.

Figures given by Robert Kates of Clark University indicated that between them floods, tropical cyclones and drought cost the world a good \$30 billion each year, claiming the lives of some 250,000 people, 95% of them citizens of the Third World. While the absolute costs of these disasters are many times greater in developed than in underdeveloped countries, in terms of GNP the situation is reversed: "Climatic hazard impacts poor countries 20-30 times the rate of rich countries," Kates suggests.

While the need for research on short-term variability was recognised as the immediate research priority, there was inevitably a great deal of discussion at the meeting of the possibility (rather than the probability) of medium term changes. This brought up the debate between the "ice age" prophets, and those who see the danger of a global warming as the more immediate threat.

By the end of the meeting, both could perhaps agree that their points had been met; there seems to be a general consensus that the Earth is at the start of a potential cooling period of perhaps 10,000 to 20,000 years, possibly not an ice age in the sense of those recorded in geological time, but still a major, long-term change.

At the same time, there was no doubt of the feeling of the meeting as a whole, regarding the possible combined effects of CO₂ emissions and those of other pollutants such as nitrous oxide and many chlorine compounds, including the already notorious chlorofluoromethanes. How little is known about the real effects of all these substances is evident from a note in the report of the working group concerned, that "it is possible that some processes could lead to a cooling" (rather than a warming as with CO₂) "of the atmosphere".

Despite this uncertainty, Ralph d'Arge of the University of Wyoming offered estimates of the economic costs of climatic change. Giving sets of figures for a drop of 1°C, he calculated that losses in rice production could only be offset by an investment of \$19 billion—and rice is the staple crop of the majority of the world's poorest people.

Yet perhaps even more significant, as indicating the knife-edge of climate on which many national economies are balanced, are his figures for softwood

production in USSR: a drop of 1°C would require an offsetting investment of \$28 billion, whereas only a half degree rise would give a \$13 billion bonus.

Where urban wages are concerned, this differential is even more marked: for the United States alone, d'Arge's figures jump from a loss of \$73 billion to a rise of \$31 billion. So it is not surprising that another conclusion of the conference was that planners, in the industrialised countries as well as those of the Third World, should take climatologists far more into their confidence than they do at present.

Not irrelevant in this connection was a response made to B. J. Mason, Director of Britain's Meteorological Office, when he remarked that variability such as the hot dry summer of 1976 need not be so disastrous: whereas certain British crops did badly, others so improved that the total loss was slight. It was the sole Iranian at the meeting who pointed out that perhaps this was because many crops grown in Britain are at the limit of their natural range, and need a warm summer to be really profitable.

Fascinating data on medium term climatic variation was put forward in the Chinese paper, based on studies of fluctuations over much of the last 5,000 years. Mean temperatures are believed to have varied over a range of two to three degrees—as great as that foreseen under a prolonged "greenhouse

effect" today. At the same time, Chinese scientists studying more recent records believe they have identified a number of short-term cycles of from two or three to 11, 22, 36 and 80 years for various parameters in different parts of their vast country with, it is admitted, an extraordinarily wide range of normal variation.

Inevitably, a good deal of attention was paid to the use of computers as the main tools in forecasting, especially perhaps over longer ranges of time, although it was agreed that there is an urgent need for better models to work to. Moreover, although no one was so crude as to point this out, an industrialised country such as Britain may well spend as much on a single giant computer as many, if not most, Third World countries have for their entire annual budget in meteorological services.

This point, at least, was reflected in the final Declaration of the Conference, with a call for assistance to these countries through training and the transfer of appropriate technologies without which they cannot participate fully in the proposed World Climate Programme. This programme, a bare outline of which was appended to the Conference Declaration, will be discussed by the WMO Congress when it meets from 30 April for four weeks, with a view to reaching decisions about content and funding.

Peter Collins

Call for world (non-nuclear) energy organisation

THE potential dangers of the rapid growth of nuclear energy on an international scale are so great that there is an urgent need to establish a global body to co-ordinate and stimulate the development of non-nuclear sources of energy, according to Dr Joseph Rotblat, emeritus professor of physics at the University of London, and a leading member of the Pugwash organisation.

Speaking at a meeting in London last week organised by the environment division of the Institute of Biology, Professor Rotblat said that although a global energy body already existed in the International Atomic Energy Authority, it existed to promote one form of energy—nuclear. No similar body existed to encourage other energy forms. "It is high time that the balance was restored", he said.

A large expansion of nuclear power would greatly increase the chance of nuclear war, said Professor Rotblat, since almost every nation would have access to plutonium, and would also have the technology necessary to make nuclear weapons. "In the long run nuclear energy is not compatible with the survival of civilisation", he said.

Fortunately the recent slowdown in global demands for energy meant that the expansion of nuclear energy was likely to be much slower than earlier predicted. However the risks of proliferation were still increasing, particularly since several countries had made the export of nuclear energy an important part of their economy, while the demand in third world countries had been stimulated by the "promotional activities" of the International Atomic Energy Agency.

"The most positive thing we could do to reduce the risk of nuclear war would be to encourage countries to opt for non-nuclear sources of energy. A global organisation devoted to this end would be important to give the same aura of respectability to non-nuclear energy sources as is at present given to nuclear energy", Professor Rotblat said.

Professor F. W. Spiers of the University of Leeds told the meeting that measuring background levels of radiation provided an important yardstick for studying the health effects of society's nuclear activities. Whether background radiation was a source of cancer was an open question, he said. "Although we would not anticipate it to have much effect when there are so many other causes of disease".

Levels of background radiation also provided a lower limit for the 'doubling dose' for different cancers, since if this dose was estimated at less than the background level, it would imply that the background radiation was responsible for more than the observed incidence of cancer.

David Dickson

Soviet space effort is strictly for the cash, not the glory

ACCORDING to TASS, the flight programme of Soyuz-32—launched on 25 February—includes docking with the Salyut-6 orbiting station and checking it for a possible further mission aboard the station. This suggests that the Soviet planners are anxious to get their last kopek's-worth out of Salyut-6, which has already been in orbit for almost 18 months.

Although the finances of the Soviet space programme are never published, current Party doctrine stresses that all branches of science should direct their research towards the practical needs of the national economy. The economic pay-off from the Soviet space programme was therefore the keynote of a press conference in Moscow last month given by chief Training Officer Vladimir A. Shatalov and cosmonaut Vladimir Kovalenkov.

According to Shatalov, "the greatest economic impact, the greatest benefit so far can be derived from research in near-Earth space and in the operation of orbital stations". This, he said, would remain the basis of the Soviet space programme for the next few years, because such questions "really do bring considerable, obvious benefits even now".

Illustrating such benefits, Kovalenkov mentioned observations from orbit of dust storms and meteorological and oceanological processes. When observations of the oceans began, he and his fellow-cosmonauts were not told what they were supposed to be observing. They had to work out by trial and error such practical matters as the best porthole to use in relation to the Sun's position. After some time, he said, it was possible to understand "to some extent" the ocean currents, and hence to identify resources of phyto- and zooplankton—to the ultimate benefit of the Soviet fishing fleet.

Observations from orbit of ocean vortices, Kovalenkov added, had led to an oceanological expedition to the Atlantic last summer. From subsequent reports, it appears that this expedition established the existence of isolated closed spiral currents, with diameter up to 200 miles. However these are predominantly in the Bermuda Triangle area, and the unbiased observer should remember that the Soviets, being good dialectical materialists, are at pains to find a physical explanation of the supposed Bermuda Triangle disappearances.

The observation of such processes from space will be a major task of the first Soviet unmanned oceanographic

satellite, Kosmos-1076, launched on 12 February. Soviet space planners have always stressed the great potential of unmanned craft and probes. The US Apollo moonflights, for example, were presented in the Soviet media as a waste of funds. The *Luna* spacecrafts and *lunokhod* rovers, it was stressed, could do all that a manned Soviet mission might do, at half the cost. Kovalenkov's remarks would suggest, however, that without the recent long-term manned Salyut missions, the programme of the unmanned Kosmos-1074 might well have been a somewhat hit-and-miss affair.

Earthquakes are another Soviet concern. A team at the State Nature Centre are using photographs from the Salyut missions to predict earthquakes in the Soviet seismic zones. A spokesman from the centre explained recently on Moscow radio that the seismic zones were first observed visually by Yuri Gagarin. Since some 15% of the terrain of the USSR is seismically active, while some 30% of the population live in these areas, earthquake prediction from satellite observations, he said, could produce "tremendous" savings in construction costs. Preliminary work along these lines was begun by the Salyut-6 crews last year.

Even the exotic triple Cd-Hg-Te semiconductor crystals produced about Salyut-6 in the joint Soviet-Polish "Syrena" experiment have their practical use. They have been handed over to the Polish Institute of Mining Safety, to be used in producing infrared-sensitive pyrometers.

Salyut, it would therefore seem, is paying its way. Indeed, Shatalov himself admitted as much in a recent interview with the Bulgarian daily *Otechestven Front*. Much of his state-

Soyuz-32 send off: Cosmonauts Lyakhov (top) and Ryumin before Sunday's launch.

ment was, naturally, devoted to the training of the Bulgarian cosmonaut candidates, in the Interkosmos programme, but in referring to the work of the Salyut crews "including the international ones" carrying out extremely valuable observations for the national economy, he implied that, in his opinion, from now on the programme would be operating essentially on a break-even basis.

Looking to the more distant future, Mr Shatalov noted that, with bigger spacecraft, there would be a stricter division of crews into scientific and operational personnel. This would cut considerably the training demands on the individual members of the crew who would now need to qualify only as scientists or, alternatively, as spaceship operatives. Ultimately, he said, a whole "Aeroflot-type" back-up organisation would have to be set up as well, to handle the terrestrial processing of the flights.

Vera Rich

Space shuttle may be six months late

A STUDY group of the US National Academy of Sciences predicts that engine problems mean the space shuttle's first flight, officially planned by NASA for November this year, is now unlikely to take place until April 1980.

In a report prepared at the request of the Senate committee on science, space and technology, the group says it is particularly concerned that the engine that will actually fly in the space shuttle will not be the same configuration as that currently being tested, and that, in the circumstances,

plans to perform flight certification tests on the engine, which will be used among other things to help launch the European Space Agency's Spacelab, are premature.

"The only rational option, for safety's sake, is to reschedule the formal flight certification until the configuration is fixed," Professor Eugene E. Covert, professor of aeronautics and astronautics at the Massachusetts Institute of Technology and chairman of the National Research Council group which prepared the report, said last week. □

Supreme Court to hear benzene exposure case: The US Supreme Court has agreed to review an appeal court ruling which struck down the Occupational Safety and Health Administration's strict new limit for benzene exposure in the workplace. The Fifth Circuit Court of Appeals in New Orleans—whose reputation is pro-industry and anti-environmentalists—decided that the limit was invalid because OSHA did not provide a reasonable cost-benefit analysis for it. The industrial groups which challenged the limit estimated that it would cost them \$500 million to comply with the new standard and claimed there was no evidence that lives would be saved by it. The Government argued unsuccessfully that current scientific knowledge was insufficient for OSHA to predict accurately the number of lives saved by a given reduction in exposure to harmful chemicals. If the Supreme Court upholds the decision, the basis for government regulatory activities could be seriously undermined.

Rothschild's Dimpleby lecture on risk is attacked:

"In view of the highly biased nature of Lord Rothschild's lecture we were shocked to learn that the Atomic Energy Authority is distributing copies of (the lecture) through its liaison office in Washington and we call upon you to stop its distribution forthwith" said the UK office of Friends of the Earth in a letter to UKAEA chairman Sir John Hill last week. Czech Conroy, Energy Campaigner of FOE, first raised the protest on 23 February at a lecture given by the UKAEA's health and safety adviser, Professor F. R. Farmer, to students at the Royal College of Art. Conroy pointed out that Rothschild's talk was based in part on "the severely discredited" Inhaber report prepared for the Atomic Energy Board of Canada on the risks of energy production and that Rothschild's talk had been widely criticised in the scientific press. Conroy also protested that in spite of these criticisms the Authority had published the lecture without comment in its monthly magazine, ATOM. The editor of ATOM, who happened to be in the audience, offered to publish a critique of the talk and Friends of the Earth requests in its letter that this be agreed formally. The UKAEA is not yet prepared to comment on the request.

Lord Rothschild

According to the Politics of Health Group of the British Society for Social Responsibility in Science, drug companies are the most profitable industrial enterprises. In the UK for 1975, rates and returns were estimated at 21.4% (Industrial chemicals were second at 16.2%). In 1972, Boots and Beechams showed 54% and 41% returns respectively on capital employed.

(*Insult or injury?* by Charles Medawar. *Social Audit*, 9 Poland St, London W1V 3DG; £1.50.)

German President draws attention to jobs problem: The President of West Germany, Walter Scheel, addressed the Wissenschaftsrat ("Science Council") that advises government on higher education policy on 25 January about the employment problems of young scientists. He hinted that the Heisenberg Programme was not a complete solution. This programme was recently devised by the Deutsches Forschungsgemeinschaft to keep at university those who had won their "habilitation" (right in principle to a university post) but had no job. Only some 70 people had been awarded Heisenberg fellowships so far. "Industry as well ought to be at least aware of this problem", Scheel said. "Perhaps there will be an opportunity to increase exchanges between industry and the universities." However, he added: "We cannot easily refute the claim that not enough basic research is being done in the Federal Republic." And casting a glance at the well-established principle of academic freedom in German universities, he said: "It is the right and duty of the state to insist upon some coordination in basic research". However this would not reduce the freedom and dignity of research. (*Wirtschaft, Wissenschaft, Politik* 5 February 1979.)

Porton Down transfer causes redundancies: The transfer of the Microbiological Research Establishment from the control of the Ministry of Defence to the Public Health Service Laboratory Service Board is expected to reduce the staff by 25% from 300 to 223. Although called "natural wastage", the redundancies include at least 10 senior principal scientific officers within five years of retirement. Most of the job losses are being contested by the Transport and General Workers Union which represents the laboratory assistants involved in the transfer. The Ministry of Defence says that no jobs will be lost through the move except "for some who want voluntary redundancy".

Social Audit audits UK food and drug companies: Social Audit Ltd, a London-based non-profit organisation, has issued a stinging critique of British drug company marketing practices in the Third World. Supporting the World Health Organisation's criticism of the selling of "inessential" drugs in Third World markets (8 February), author Charles Medawar further cites the sale of drugs specifically banned in Britain and suppression of information about dosage and side effects as examples of "disgraceful standards of advertising and marketing by UK companies in the developing countries". Medawar emphasises that drug expenditure, typically 20–50% of a country's health budget, can do little to ameliorate health problems caused by poor sanitation and malnutrition. Preventative measures and ultimately "political and economic solutions" are needed, he says. The Association of the British Pharmaceutical Industry calls the report "an unjustified smear". The ABPI says that, given the confused state of research, there are justifiable differences in the requirements set by different governments.

Oil from coal feasibility study launched in UK: The National Coal Board and the Department of Energy of the UK have signed a financial agreement to cover the cost of creating an engineering design and feasibility study for the construction of two coal extraction demonstration plants capable of processing 25 tonnes of coal per day. The two processes which have been developed to the laboratory stage are liquid solvent extraction (petrol, diesel fuel, kerosene) and super critical gas solvent extraction, a new process that will produce the aromatic compounds, benzene, toluene and xylene, as well as chemical feedstocks for plastics, rubbers, artificial fibres and paints. The Government will put £800,000 towards the total cost of £1.2 million. The actual cost of construction and operation of the two plants, to begin in 18 months, is estimated to be £30 million. Sir Derek Ezra, chairman of the National Coal Board said at the signing ceremony: "Looking at the future availability of oil in terms of world reserves, and currently at the situation in Iran, who can say that the need for this new technology may not emerge sooner than we think?"

'Britain alone cannot end poverty, but it may be able to make a contribution to its end'

Adrian Moyes of Oxfam calls for a transformation of our 'charitable' approach to foreign aid and Third World technology

THERE'S a story of a motorist who stops to ask the way to Andover. The person he asks replies: "If I were going to Andover, I wouldn't start from here." Similarly, anyone trying to help the very poor in the Third World wouldn't start from Britain; most of what needs to be done has to be done by people and governments in the Third World. It is an illusion to think that the wonders of British science and technology can, on their own, do much to benefit the very poor. Whether they do so, depends on the political will in each Third World country.

The use of technology by the very poor has social and political costs. If there are fewer poor people, there may be fewer people prepared to work at low wages for land-owners or manufacturers. Small-scale local production may mean a smaller market for big local manufacturers or multinationals. Urban interests may block investments that will boost agriculture, urban bureaucrats may frustrate policies to direct technology to the poor.

A lot of people benefit from the way that Third World societies are variously arranged at present. They are the people who control the means of production; who own the land or the factories or the transport facilities; who have the money to lend or invest—or to buy modern technology products. They want to keep things that way.

They ensure that there are operating theatres for the townspeople, instead of dispensaries for the rural poor; that R & D is directed to sophisticated or luxury goods and large scale industry; that there is social recognition and praise for research workers who follow international science. They give low priority to extension services and small industry programmes. Foreign investment, some of it from Britain, contributes to this. As *Nature* has put it; "It skews decision-making to favour research and development policies—for example those concentrating on capital rather than labour-intensive production techniques—that benefit the upper and intermediate groups in society, but have little impact on the plight of the poorest".

Technology is a necessary condition for development, but it is not a sufficient one. It cannot get round the need

for political reform, for example by increasing yields so high that even small plots of land become viable and land reform would be unnecessary. Technology is not like that; it cannot solve political problems unless there is political will to solve them.

As a result, most Third World science and technology bears little upon the problems of the very poor. And most scientists and technologists go along with that. They tend to enjoy rather low social prestige (unlike, say, lawyers)—so they turn to the world of international science to get their standing. They go for prestige subjects that will (or at least may) lead to international recognition. Traditional technology and the needs of the poor seldom involve such subjects.

On a personal level too the pressures work against the sort of science and technology that might benefit the poor. Scientists and technologists like the comforts and stimulus of the city; they do not want the inconvenience and discomfort (and perhaps health risks) of spending much time in slums, or in poor, often remote and unpleasant, parts of their country.

There is not a great deal that outsiders can do about all this. It is not very productive for outside governments to adopt the role of championing the Third World poor against the rich in their own countries.

The difficulties are considerable, but they need not make us despair—Britain alone can't end poverty, but it may be able to make a contribution to its end—it's possible, after all, to get to Andover, even if you start from here.

In the spectrum of technology which runs from the most advanced to the most traditional, Britain's balance of advantage is greatest at the advanced end—so perhaps it is here that Britain can contribute most. Some relatively advanced science and technology can, if social and political conditions allow, benefit the very poor. Examples are education by satellite; the manufacture, storage, and testing of drugs, insecticides, contraceptives; even the equipment needed to devise a better differential for a trishaw; and in the future micro-processors and solar cells. Maybe Britain should concentrate on developing and adapting this type of technology and leave the type of technology that is actually used by the very poor to the Third World countries to handle for themselves.

The drawback to this approach is that left to itself, technology usually favours the rich. It seems to be quite a general rule that if you add to technology to an inegalitarian society (and most Third World—and many other—societies are inegalitarian) the result is increased inequality. This happens because technology is used primarily by those who can afford to take risks—the very poor can't; for them conservatism is life insurance. The miracle seeds of the Green Revolution benefited mainly the farmers who could afford the fertilisers, the irrigation and the pesticides.

The rich are also favoured because new technology tends to drive out old. In doing so it may deprive some people of their livelihood even though at the

Imperial past: is our technology just colonialism in a modern guise?

same time it benefits many of the very poor by providing cheaper and/or more durable products. The mass of consumers benefit from plastic buckets and plastic sandals, but the producers lose work and maybe jobs.

In the 60s Indian metal-workers began making metal dishes and utensils out of aluminium, instead of the "traditional" but increasingly expensive brass and steel. The plates could easily be cut and shaped with simple machines and tools. They were sold in the villages, often by the workers themselves. It cost about £100 to create one job—an ideal application of appropriate technology it might be thought. But the aluminium came from Birla, India's second largest industrial consortium, and so Birla was alerted to the new market. It began making dishes from anodised aluminium. They sold better because they were shiny. That killed the village version.

So if Britain is to implement its policy of More Help for the Poorest,

it cannot merely concentrate on the sort of technology it is best at—and hope the benefits will trickle down. It must take more direct steps to ensure that the very poor are able to benefit from technology (if they want to).

This requires recognition of the need to strengthen and develop traditional technology, rather than using imported technology to downgrade and maybe destroy it. Traditional technology is much stronger than many scientists and technologists (including Third World ones) think. It includes a wide range of skills (ironwork, waste recycling, hygiene, food preservation), a vast amount of local knowledge, and (provided there is little or no risk) a surprising amount of experimentation (often disparagingly referred to as trial-and-error). The way to help the very poor to make greater use of technology is to help them see how much they know already, and to encourage them to adapt that—and supplement it with new technology

from outside.

A good example of this approach comes from Tanzania where a team spent two months in a village helping the villagers to analyse their own storage problems and devise their own methods of improving them. The team based its activities on the belief that the villagers themselves could go a long way towards solving their own problems on the basis of their own skills and resources. They returned to the villagers in a systematised form all the information they got from them, thus giving them confidence that they possessed a concrete technology.

The villagers were not overwhelmed into accepting the team's suggestions: they rejected many of them, including air-tight stores and communal storage, and picked and chose from along their own practices and the team's suggestions so that the end result was something they had designed themselves.

At the end of the two months, 15

NATURE abhors a vacuum. During the 1939-45 war, urban sites devastated by enemy bombs were rapidly covered with vegetation. The number of species of plants and animals which appeared without any help from man was surprising. Within a few years even trees grew up among the rubble, and provided cover for insects and birds, including rarities like the Black Redstart, several pairs of which nested and reared their young within the boundaries of the City of London.

Scientists made some interesting ecological studies of these sites, and city workers interested in natural history derived pleasure looking at them during their lunch breaks. Economic pressures have caused these oases to be destroyed, to be covered with concrete and asphalt, with buildings and car parks. Opportunities for ecological studies or rural refreshment in our cities has thus been greatly diminished.

Fortunately, however, there have been encouraging developments in the opposite direction. In 1977, in connection with the Queen's Silver Jubilee celebrations, a working party was set up to consider the use of neglected areas of land in London for community purposes. The main drive came from Max Nicholson, for many years the Director General of the British Nature Conservancy. He was chairman of the working party's Environmental Committee. This has several interesting projects in hand in various parts of the city, but the one which appeals to me is the William Curtis Ecological Park in Southwark, near the Tower Bridge and just across the Thames from the Tower of London.

Rus in urbe

KENNETH MELLANBY

Until just over a year ago this three acre site was an unattractive lorry park covered with an uneven surface of hardcore, an unpromising area for ecological study. Most of the hardcore and rubble has been removed, to be replaced with soil. This has been carefully landscaped with undulations and valleys, and a good sized pool, surrounded with marshy ground, has been constructed.

Those managing the site had difficult decisions to make—to plant or not to plant. Wartime experience showed that a good cover of plants would quickly appear without human intervention. However, they wished to encourage native species. Unfortunately disturbed sites in London, as well as in remote oceanic islands like Mauritius, or in protected National Parks in Australia, often attract the wrong species. When visiting this Park recently, I saw that the commonest plants developing on

nearby waste ground were the Oxford Ragwort, a native of Italy, first recorded in England in 1794, and rapidly spread when the railways were constructed in the nineteenth century, and Buddleia, only introduced from China in about 1890, and now a rampant weed in Britain.

The Ecological Park has some areas left for spontaneous regeneration, but most of it is being carefully managed. Many native trees and shrubs have been planted, unfortunately not always successfully as the area has a surprisingly low rainfall and artificial watering is difficult. Wild flower seeds unlikely to arrive unaided have been scattered, and young plants are beginning to appear. The pond is already colonised by insects and invertebrates one might not expect to find in such a location. A kestrel nests in the one remaining large tree, all that is left from the rural countryside built over in the last century.

It will be some years before the park resembles in any way the beautiful fields and woods which once existed nearby, but it already provides unique facilities for local children, brought up in a concrete jungle, to get first hand experience of real ecological problems. Perhaps it will also inspire park authorities in other cities to set up more semi-natural areas to complement their tidy lawns and regimented rows of colourful bedding plants. There have indeed already been some such developments, in Glasgow in Scotland in particular. The virtue of the William Curtis Park is that it shows how much can be done with a small and unpromising parcel of wasteland.

new village-designed grain stores were built and in use, several other improved stores were built, even the poorest were using insecticide, the village storage committee had set up a research project to monitor results, the village had agreed to teach 15 other villages to analyse their storage problems, and the committee held a seminar at the university. "It was at this point, recounts the Report on the project, that the committee members really began to see themselves as storage experts"

These Tanzanians had begun not only a process of improving their storage practice but also a process of using their own and outside technology for their own benefit.

Outside technology however cannot usually be applied directly; its principles and techniques may be valid worldwide, but their use varies as much as the people who use them. When technology is transferred from one society to another, the principles and techniques remain the same, but they are re-arranged and combined with a different set of social and economic activities—to make a technology that has been "transformed"

In order to "transform" a technology, people need a range of possibilities from which they can select and test those most relevant to their needs, combine them with elements from their own technology, and work out the new social and economic arrangements needed.

The new technology may mean more time for women, or more work for

women; more money for everyone, or more money for one or two people; less free time in the festival season, too much work in the peak weeding season; community work to empty latrines, community contributions to pay for a maintenance worker. It may mean new institutions at family level, as when a new agricultural technique tends to transfer work from women to their husbands; at village level, as when village meetings have to choose somebody to go for training as a village health worker; or at local government level, as when the technicians are needed to maintain village pumps, cover a whole district and have to be organised from a central office.

Outsiders (such as people in Britain) can develop appropriate technology—techniques or hardware which perform needed tasks. But only the people who are to use the technology can transform it; only they can adapt their ideas (on the role of women for instance, or the importance of festivals) and their social and economic arrangements.

How then can Britain help the very poor to develop their own technology and transform outside technology? The answer lies in a new sort of programme—a programme whose leading edge is in the slums and villages of the Third World where the poorest are. Field staff, many of them local, would seek out, stimulate and finance projects such as the Tanzanian grain-storage one described earlier, helping it to grow into a countryside system, including (if need be) training for extensionists and laboratory and workshop facilities.

The field staff would have access to funds not tied to British salaries or equipment, and the programme would be able to finance non-government bodies in the Third World. There are various ways such a programme could be organised—as a development of one of the Ministry of Overseas Development's existing units, as a new Council for the Use of Technology Overseas (or something), or as a non-government body (perhaps a multilateral one).

A programme of this kind would be quite a change from Britain's present aid for science and technology. The basic premise in Britain is that *they* have the problems, *we* have the solutions. Technology made us rich; we have only to apply it to make them rich. The tradition in Britain is to do things for the poor in the Third World—a kind of charity even when run by the government.

But it is not much help to make people the passive recipients of a technology designed elsewhere; there needs to be a close connection between the development of a technology and the society in which it is to be used. We should be concerned not so much with the appropriateness of a particular piece of technology, as with the appropriateness of the process of technical change. That is what the new programme would be about. □

Stockholm institute supports Third World scientists

Dr I. M. Nitis, at the Udayana University of Denpasar in Bali, is working on stylosanthes as a companion crop to cassava. He has discovered that the extra green feed produced by the combination of the two crops could support one or two yearling Bali cattle per hectare for a year. His work has been financed by three grants, ranging from \$555 to \$6,600, from the International Foundation for Science (IFS). "The IFS only gives a little money, but it leaves me to work quite independently", he says. "The beauty of the foundation is that it helps young third-world scientists just starting their own research. If their project is successful, a bigger organisation—the UN Food and Agriculture Organisation, for example—will pick them up." Dr Nitis is one of 250 young scientists in 44 developing countries receiving support.

"Our grants have been limited to research in applied biology and agriculture—work which could be carried out in the villages", explained Professor Sven Brohult, founder and President of IFS. "We want to establish self-

Wendy Barnaby reports on the work of the International Foundation for Science

supporting units on the farms and in the villages. It's like the old Chinese experiment of having everyone self-supporting on a small scale so that nobody actually starves. We must avoid contributing to urbanisation and bureaucracy. We leave big investments to the big organisations. Our idea is to encourage indigenous, simple technology."

So far, grants have been given under six categories: aquaculture; animal production, vegetables, oil seeds and fruits; afforestation problems; fermentation and methods for food preparation; and natural products. "We feel the work has been rather successful in these fields", added Professor Brohult, "and are thinking of going into another rural construction. On a very simple level, of course. How to construct a fishpond, for example: you have to have a certain slope around the walls.

And we could help in supplying energy to rural communities. Using simple means to dry fish with solar energy."

To qualify for a grant, a project must be relevant to the needs of a developing country and the researchers must be native to, and carry out their work in, a developing country, where their salaries are paid by the institute that normally employs them. All applications are adjudicated by voluntary scientific advisers.

This sort of volunteer work is gratefully received: IFS's total budget last year was just under \$1 million. The money came as government grants from nine countries: Sweden, Canada, France, the Federal Republic of Germany, Belgium, Norway, the Netherlands, Nigeria and Switzerland.

Although the day-to-day running of IFS is left to its small, Stockholm-based staff, guidance and ideas are provided by about 50 member organisations' academies of science around the world. The most recent to join, to Professor Brohult's great delight, is the Royal Society in London. □

GMAG: NIH guidelines are not the way

SIR,—Professor Alan Williamson is well within his rights to complain (1 February, page 346) that there was “no real debate” about the proposed basis of GMAG’s new way of working at the public meeting on 21 December, although it is by no means clear at whom the complaint should be directed. By inference, GMAG is somehow to blame. Professor Williamson could just as well have blamed those among his colleagues who chose to use up what time there was in echoing (and amplifying) what the platform had already acknowledged—that there must be special arrangements for some (but not all) homogenic experiments. He might also blame himself for not having brought up the issues to which he now draws attention.

Of these, perhaps the most important is Professor Williamson’s assertion that the UK could with advantage adopt the NIH guidelines and be done with further introspection. It is therefore worth saying that the NIH guidelines are in several respects defective, at least if one supposes that some of the conjectured hazards of genetic manipulation may (or might be) real. First, their classification of animal virus experiments is irrational, and takes no account of conjectured immunological hazards in particular. Second, the potential importance of expression compared with mere replication has been entirely overlooked in the “broadly based public debate” that Professor Williamson admires. Third, even the new NIH guidelines are not constructed in such a way that what must be presumed to be a growing class of experiments without risk can be progressively identified and excluded from rigorous restraint.

I am one of those who believe that if GMAG does not change its procedures soon, we shall find that events force on us a decision between the NIH guidelines and doing the research elsewhere. It is of course ironical that we should be faced with such a choice when the hazards of genetic manipulation remain conjectural. In my opinion, however, it is disingenuous of Professor Williamson and other would-be genetic manipulators to complain at the constraints which they invited a mere four years ago. Making a bonfire of the regulations now will cause only trouble. Surely it is in the interests of the scientific community that they should be dismantled by rational means.

GMAG’s proposed way of working offers precisely such a possibility, provided that genetic manipulators will play their part in gathering the necessary data. My own belief is that if the proposed system were adopted and willingly accepted, we should find that before the end of 1980 all but a handful of experiments were no more restricted than by the requirements of “good microbiological practice”. Is not that a chance worth taking?

Yours faithfully,

JOHN MADDUX

Risks of recombinant DNA regulations

SIR,—A more appropriate title for your editorial (November 9, page 103) would have been ‘The absence of reason continues’ or ‘Reason ought to prevail’, rather than ‘Now reason can prevail’. Let me explain why I consider the regulations of the recombinant DNA technique and the new GMAG proposal as unreasonable.

● Since the risks of the recombinant DNA technique are principally in the realm of hypothetical scenarios and science fiction, it is totally unreasonable to propose any complex regulations.

● GMAG is proposing to estimate the imaginary risks of various types of experiments, but totally ignores the true risks of regulations themselves. As I have discussed before (*Trends in Biochemical Sciences* 3, NZ43; 1978), the regulations lead to many real dangers to science and society while their benefits are restricted to supporting the livelihood of the bureaucrats who administer the regulatory machinery. It is totally unreasonable to institute regulations without first evaluating the benefit-to-risk ratio of the proposed regulations themselves, and this ratio in the case of recombinant DNA regulations approaches zero.

● As wisely argued by J. D. Watson (*The New Republic* 180, 12; 1979) it is folly to control any human endeavour which may benefit society, just because it is impossible to provide a perfect proof that no risks exist or can be imagined. There is a high probability that such bureaucratic controls will be detrimental to the best interests of society, rather than having any benefits.

The GMAG proposals on the complex numerical estimations of the purely imaginary risks bear a resemblance to the Hans Christian Andersen fable on the ‘Emperor’s New Clothes’ and appear to be a rather pathetic example of where the recombinant DNA folly could lead us. Let’s hope that at the end reason will prevail and all regulations will be converted to a one-sentence statement proposed by D. Stetten, the first chairman of the NIH Recombinant DNA Advisory Committee: “The conditions of containment appropriate for any recombinant DNA experiment are those which are dictated by the most virulent or dangerous organism entering into that experiment”.

Yours faithfully,

Wisdom in universities

SIR,—Your leader ‘Converting intelligence into wisdom’ (25 January, page 251) draws undeniably sound conclusions about our lamentable shortage of far-sighted generalists. But in my view you err in claiming that education must be ‘immensely wasteful’ to be effective. It is simply not true that most of what we learn at school or college helps illuminate future thinking in an indefinable way. Quite the converse: the insistence on specialist teaching, parrot-fashion learning and the unrelenting adherence to cumbersome orthodoxies in the academic world are the antithesis of what education ought to mean, and drives out of the minds of all but the most stalwart student any aspiration to true independence or heterodox creativity.

Teaching was originally the responsibility of elders who were accepted as sources of wisdom. It is now a source of profitable employment for those who, all too often, lack the wisdom to do anything better. University teachers are rarely taught to teach. University students who do well in their examinations often look back to realise that they did so in spite of how they were taught, rather than because of it; and few people will argue with the claim that most of what they were taught was distinguished by its irrelevance to conditions in the real world. I have recently been looking into some of the attempts made by universities to get together with industry, for example, in an attempt to make available the wisdom that we like to imagine lurks in the academic fold. In many instances the level of common literacy (to cite just that) is as low in the university-sponsored material as it is in the most backward corner of narrow-minded industry. The inefficiency of universities with regard to staff appointment procedures, administration and communication is remarkable—but is entirely in accord with what I have come to expect.

This is not to say that all university departments are incompetently run. But the very fact that *any* are, undermines what faith society ought to have in the seats of learning. Until there is a thorough reappraisal of what education should mean there is little chance of injecting excitement and liveliness into the academic world. There will be few generalists as long as there is no market for them; and until the unthinkable occurs, and the reappraisal you call for in your leader begins, the opportunities for real progress and revolutionary new insights into man’s predicament will remain unwanted, unfashionable, and frankly embarrassing.

It is, I fear, impossible to upset an apple-cart that is so large, and so weighed down with passengers who are enjoying the apples. It’s fun trying, though.

Yours faithfully,

BRIAN J. FORD
Science Unit, Cardiff, UK.

Artificial reaction centres to mimic photosynthesis

from Roderick K. Clayton

In photosynthetic tissues, tens or hundreds of molecules of chlorophyll and other pigments cooperate in absorbing light energy that is delivered to a single photochemical machine. The concept of a photosynthetic unit, a photochemical reaction centre together with its share of light harvesting or 'antenna' pigments, was advanced by R. Emerson and W. Arnold in 1932 (*J. gen. Physiol.* 16, 191) to explain the yield of photosynthetic oxygen evolution by algae exposed to brief, intense flashes of light. It was C. B. van Niel who proposed, on the basis of comparative biochemical studies of bacterial and green plant photosyntheses (see *Adv. Enzymol.* 1, 263; 1941), that the photochemistry is oxido-reductive: light energy, absorbed by chlorophyll, drives a separation of oxidising and reducing entities. We now know that this photochemical oxido-reduction is the transfer of an electron from chlorophyll (or bacteriochlorophyll, in the case of the photosynthetic bacteria) to an acceptor, often a quinone. Photochemical reaction centres are pigment-protein complexes in which some of the chlorophyll is specialised to react in this way. The reaction centres are embedded in membranes that also carry the antenna pigments and the components needed for electron transport, proton translocation, and ATP formation. Quanta absorbed by the antenna pigments migrate to the reaction centres and initiate photochemistry. The products, oxidised chlorophyll and reduced acceptor, serve as starting points for the secondary events that provide ATP and reduced pyridine nucleotides, which in turn sustain growth.

The first direct sign of photochemistry in reaction centres was the reversible light-induced bleaching of an absorption band near the long wave absorption maximum of chlorophyll or bacteriochlorophyll. This was reported by L. N. M. Duysens using photosynthetic bacteria (bleaching of 'P890'; thesis, State University, Utrecht, The

Netherlands, 1952), and by B. Kok using green plant tissues ('P700'; *Biochim. biophys. Acta* 48, 527; 1961). The reversible bleaching was a small fraction of the total absorbance, most of which was due to antenna chlorophyll. Reaction centres of photosynthetic bacteria were first isolated as spectrophotometric entities by selective degradation of the antenna bacteriochlorophyll and consequent exposure of the absorption spectrum of the reaction centres (Clayton *Biochim. biophys. Acta* 75, 312; 1963; Loach *et al. Photochem. Photobiol.* 2, 443; 1963). They were first isolated as chemical entities through dissolution of the membranes by means of detergents and subsequent fractionation (Reed & Clayton *Biochem. biophys. Res. Commun.* 30, 471; 1968). Reaction centres have not yet been isolated from green plant tissues for either of the two photosystems. However, the detailed chemical and physical analyses of purified bacterial reaction centres (see *The Photosynthetic Bacteria* (ed. Clayton & Sistrom) Plenum, New York, 1979) have provided insight into the composition and functioning of the reaction centres of photosystem 1 and photosystem 2 of green plants (see *Brookhaven-Symp. Biol.* 28, 1976).

Reaction centres isolated from photosynthetic bacterium *Rhodospseudomonas sphaeroides* are pigment-protein complexes in which four molecules of bacteriochlorophyll, two of bacteriopheophytin (pheophytins) are chlorophylls in which the central magnesium atom has been replaced by two protons), one molecule of ubiquinone and one iron atom are bound non-covalently to a protein composed of three polypeptides, total molecular weight 10^4 . In the first photochemical step following excitation, an electron is displaced from two of the four bacteriochlorophylls, acting cooperatively as electron donor, to one of the two bacteriopheophytins. The electron moves on to ubiquinone in less than a nanosecond. The quantum efficiency of this process is close to 100%. The products, dimeric bacteriochlorophyll cation ($B_2^{+ \cdot}$) and anionic ubisemiquinone ($Q^{\cdot -}$), are stable against a back-reaction for about

1/10 in the absence of external electron donors or acceptors. In the living cell these products interact with secondary electron carriers in less than a millisecond.

The elucidation of photochemical mechanisms in reaction centres has been aided by studies of the properties of chlorophylls and pheophytins *in vitro*, and our new knowledge of how reaction centres behave has in turn guided attempts to construct artificial reaction centres that mimic the natural ones in terms of reactions, rates and efficiency. One motive for this is to invent a photovoltaic cell, useful for solar energy conversion, patterned after the natural system. On page 54 of this issue of *Nature* M. J. Pellin *et al.* describe for the first time an artificial system that resembles, in its composition and photochemical properties, a truncated version of the natural photosynthetic reaction centre. In the model system the analogue of bacteriochlorophyll is pyrochlorophyll *a*, chosen for its greater stability against irreversible photo-oxidation. A dimer of pyrochlorophyll *a* is linked to an alcohol derivative of pheophytin *a*, the latter acting as a hydrogen bonding nucleophile. Measurements of flash-induced absorbance changes indicate that electrons are transferred with high quantum efficiency from dimeric pyrochlorophyll to pheophytin in this molecular complex. The photoproduct is formed in less than 6 ps and returns to the neutral ground state in 10-20 ns. This is exactly the behaviour of natural reaction centres from which the ubiquinone has been removed: electron transfer from dimeric bacteriochlorophyll to pheophytin in less than 6 ps, followed by relaxation to neutral ground state bacteriochlorophyll and bacteriopheophytin in 10-20 ns. The success of this experiment suggests that the rapid and efficient operation of photosynthetic reaction centres does not depend to an exquisite degree on the angular and translational coordinates of the components. The artificial system shows promise that more stable variants of the natural system might be developed for solar energy conversion. □

Roderick K. Clayton is Professor of Biology and Biophysics, Division of Biological Sciences, Cornell University, New York.

An expanding Earth?

from W. B. Harland

THE concept of an expanding Earth belongs to this century because until the discovery of radioactivity and its application to geoscience there was no knowledge of an internal source of heat that would prevent the Earth from shrinking. Indeed, until about 1950 most geotectonic debate was between the hypothesis of thermal contraction with a reduction of radius of less than 0.01 mm yr^{-1} and a convection hypothesis for continental drift that assumed a relatively constant radius. The primary features to be accommodated were the orogenic belts with a debatable degree of convergence. So for continental drift it had to be assumed that the oceans must be expanding to maintain a steady-state Earth. The concept of convection with spreading oceans was probably first developed by Osmund Fisher (between 1881 and 1891) but not until 1933 was the concept of an Earth expanding so as to open all the oceans enunciated by Hilgenberg. This was not then taken too seriously as no convincing mechanism was proposed to account for so large a change so suddenly in the later part of Earth history. Indeed it was Carey's detailed and accurate reconstructions of continental drift especially from 1958 onwards that perhaps more than anything else, demonstrated the validity of tectonic evidence to settle the debate active since Wegener's successive formulations (between 1912 and 1928). Strangely, however, Carey's reconstructions required more ocean spreading than could be swallowed up in orogeny and so he wanted continental drift to be largely explained by an expanding Earth.

This recurring question was considered at a recent meeting in London*.

At this meeting S. Warren Carey (University of Tasmania) argued, for example, that the great circle approximately encompassing the Pacific Ocean had expanded substantially with little evidence of contraction along its length. Again, most Earth models postulate a large Tethyan Ocean that successively reduced in size through Palaeozoic and especially Mesozoic time to be finally eliminated; but Carey argued that the Tethys is an artefact formulated only to avoid an expanding Earth and that it had no reality; the same would apply to other postulated earlier oceans. He concluded that the Earth has expanded exponentially, this expansion is recognisable only in the last 200 Ma and the rate has increased to that of the present day $5\text{--}6 \text{ cm yr}^{-1}$. Carey also argued

that the main orogenic belts had begun with equatorial dispositions and that major sinistral shear took place along those lineaments. Such transcurrent juxtaposed features whose dissimilarity had instead suggested to many an oceanic gap.

In the intervening years, from magnetic striping, the course of ocean spreading has been delineated with considerable precision so that latterly the problem was to estimate how far this generation of new crust was compensated by the, much more difficult to estimate, subduction in orogenic belts. H. G. Owen (British Museum (Natural History)) has plotted the striping in a series of detailed maps that also require a more modest, but nevertheless significant, expansion of the Earth during the past 200 Ma at least. Owen's expansion is less than Carey's because he recognises the evidence of subduction zones. It might be added that most plate tectonic reconstructions seem to get by with a steady size Earth but they generally do not plot ocean floor spreading details. In this respect Owen's work is so thorough that it cannot be ignored.

To complete the series one might add a commonly held third hypothesis that the Earth is only slowly expanding (about 0.05 cm yr^{-1} as suggested by Egged, in 1969 and Holmes in 1965) so as not to affect ordinary plate tectonic reconstructions. Such could easily be accounted for by thermal expansion from radioactivity.

Tests of these hypotheses were discussed in general and in fundamental terms by S. K. Runcorn (University of Newcastle) and with rigorous quantitative and geometrical constraints by A. D. Stewart (University of Reading).

The palaeomagnetic test compares the palaeolatitudinal spacing on a continent with that on the present Earth. This assumes an inextensible continent, and a continuing geocentric magnetic dipole and would be capable of settling the question if only the errors were not too large. Results would seem to rule out any extreme expansion but might allow up to 5% over the past 200 Ma.

Earth's moment of inertia would change with increasing radius and there would be a marked slowing with expansion. Estimates of the number of days in a year have been made of around 400 days at about 400 Ma. This would not permit the recent rapid expansion hypothesis; but the critical observations on corals on which these figures are based have yet to be repeated more generally.

The principal mechanism suggested for expansion over and above what secular thermal expansion would effect is that of Dirac's decline of the gravitational constant with time. But that would hardly fit the sudden expansion of radius from 0.6 cm yr^{-1} at 500 Ma and 0.7 cm yr^{-1} at 250 Ma (respectively about 11 and 5% of Earth history and nearer 1% of the age of the Universe). An interesting test of such extreme expansion is provided from extraterrestrial bodies. The smooth lunar maria, formed at about 3.8 Ga, are preserved with no subsequent distortion as would be the case if a cosmic process were to account for a differential expansion of the Earth's crust. An extensile feature on Mars would suggest only a small expansion.

Stewart distinguished planetary interior expansion (perhaps due to decline in G) rupturing the outer shell, from general expansion of the Universe. The latter could not directly produce differential motions such as continental drift but only a change of Earth's radius of 0.5 mm yr^{-1} . A test of palaeogravity change from mineral PT systems does not seem to distinguish expansion models up to 0.5 cm yr^{-1} .

His main contribution was a rigorous quantitative study of the geometrical constraints on the interior expansion hypothesis. On a constant diameter Earth, spreading varies from zero at the poles of relative rotation between two plates, to a maximum 90° away. But on a purely expanding Earth, spreading rates should be essentially constant. It is thus possible to get a measure of the expansion rate by measuring spreading pole-spreading equatorial distance. The result is less than 0.4 cm yr^{-1} over the past 5 Ma. This would eliminate Carey's rapid expansion but not Owen's which is 0.5 cm yr^{-1} average over the past 200 Ma.

Several estimates of subduction rates were used to test the balance of crustal gain and loss. This is simply a return in more sophisticated fashion to the old problem of orogenic shortening. Here there is space only to conclude that the subduction required for a steady state Earth seems to be approximately ($\pm 50\%$) consistent with several methods applied to individual zones, and so at least half of all oceanic crust formed must have been subducted which would rule out the extreme but not Owen's expansion.

Finally Stewart's assessment of the standard palaeomagnetic test from McElhinny's data concludes a rate of expansion of radius only 0.11 cm yr^{-1} which would rule out both Carey's models. This is what most scientists

*A meeting of the Joint Association for Geophysics with the Geological Society of London was held in London on 17 January.

W. B. Harland is in the Department of Geology, University of Cambridge.

have generally concluded though one speaker questioned whether the data-set used to obtain this figure was properly chosen. But the challenge of an expanding Earth will remain until either the tests have been more rigorously repeated or the critical features of Carey's and Owen's models are incorporated in a steady-state model with or without minimal expansion.

Mechanism of platelet-collagen interaction

from J. L. Gordon

THE rapid adhesion of platelets (or of their non-mammalian counterpart, the thrombocytes) to the vascular wall when the endothelial lining is breached has been a subject of interest since Wharton-Jones showed in 1851 that thrombocytes accumulated at points of local damage in blood vessels of the frog's foot. It eventually became clear that the substance that platelets 'recognised' was a component of connective tissue, and of the various components tested only fibrillar collagen induced platelet aggregation *in vitro*. The importance of platelet-collagen interaction in haemostasis and thrombosis was sufficient justification for many research groups to study this phenomenon but its speed and specificity also intrigued some of those with an interest in cell adhesion *per se*, who joined the search for a collagen 'receptor' on platelets and for the determinants on collagen that platelets recognised.

When Jamieson *et al.* (*Nature new Biol.* 234, 5; 1971) advanced the hypothesis that a glycosyl transferase on the platelet surface mediated adhesion by forming an enzyme-substrate complex with incomplete disaccharide groups on the collagen molecule this provided a great stimulus for research on platelet-collagen interaction. Eventually, the results of further experiments (see for example Menashi *et al.* *Nature* 264, 670; 1976) made this hypothesis untenable, despite the impressive rear-guard action mounted by its proponents (Jamieson *et al.* *Thrombos. Diath. haemorrh.* 33, 668; 1975). An important factor in this debate was the discovery that an ordered, fibrillar, quaternary structure was required for collagen to stimulate platelets (for a review see Jaffe in *Platelets in Biology and Patho-*

logy (ed. Gordon) 261, Elsevier, 1976). Thus, in experiments using monomeric collagen (that is, individual molecules composed of three polypeptide chains as a triple helix) where some platelet response to stimulation (for example aggregation or secretion) was measured, collagen polymerisation was a prerequisite for activity. Hence, it was sometimes erroneously concluded that inhibitors were blocking platelet-collagen interaction when in fact they were interfering with collagen fibrillogenesis. This was also exemplified by studies with collagen subtypes which show varying rates of fibril formation: for example, type III is a much more potent stimulant than type I when they are mixed with platelets in monomeric form (Hugues *et al.* *Thrombos. Res.* 9, 223; 1976) but the potency difference is minimal if preformed fibrils are tested (Barnes *et al.* *Biochem. J.* 160, 647; 1976).

Even when it was accepted that collagen must be in fibrillar form to stimulate platelets the question still remained whether monomeric collagen (or even fragments of individual molecules) could bind to platelets without inducing aggregation or secretion. Much intellectual and experimental effort was expended on this but the results obtained were often conflicting and the discussions generated more heat than light. One reason for this was that collagen molecules and fragments readily self-associate either when free in solution or during attachment to a matrix such as sepharose beads; hence, varying amounts of pseudofibrils may be present. Platelet-collagen binding experiments are also open to the criticism that weak interactions probably do not survive the separation procedures. The main conclusion to emerge from such studies was that platelets may bind to submolecular fragments of mammalian collagen but, if so, the binding was much weaker than to fibrils. These findings were consistent with the hypothesis advanced by Lüscher *et al.* (*Ser. Haematol.* VI, 3, 382; 1973) to explain platelet stimulation by polymers. This introduced the concept of platelets interacting weakly with monomers or fragments through binding sites of low specificity and affinity; when multiple, simultaneous interactions were possible with several sites in optimal alignment (that is, in an ordered polymer with regular repeating sequences) binding was much stronger and a cellular response was induced. Polymerisation alone is not enough—platelets are not stimulated by gelatin (polymerised, but denatured, collagen). It appears that the native fibril formed *in vivo* by collagen type I or type III exhibits an

optimal configuration: platelet aggregation can be induced by $< 1 \mu\text{g ml}^{-1}$ of type I collagen in suspension. In contrast, suspensions of native type IV collagen (which has an amorphous structure) are inactive. However, if collagen types I and IV are dissolved and reassembled as SLS ('segment long spacing') fibrils they are both active platelet stimulants, with an activity threshold around $10 \mu\text{g ml}^{-1}$ (Barnes, Bailey, MacIntyre & Gordon; unpublished work). It therefore seems that the steric arrangement of collagen molecules is much more important than chemical differences between subtypes in regulating interaction with platelets.

The recent paper by Bensusan *et al.* (*Proc. natn. Acad. Sci. U.S.A.* 75, 5864; 1978) sheds some light on platelet-collagen interaction by concentrating on the platelets rather than the collagen. They induced platelet-collagen adhesion by mixing a suspension of type I native collagen fibrils with well-washed platelets, disrupted the adherent platelets by sonication, and determined what platelet proteins remained adherent. The most important platelet membrane component attached to the collagen was fibronectin, a glycoprotein of $\sim 2 \times 10^5$ molecular weight that is a major component of many cell membranes. Also present were actin, myosin and tropomyosin, which suggested that fibronectin on the platelet membrane was involved in binding to collagen and was also connected to the platelet contractile proteins. The presence of fibronectin was confirmed immunologically, and further evidence for its functional significance was obtained by demonstrating that collagen pretreated with fibronectin did not stimulate platelets, whereas anti-fibronectin antibodies induced platelet secretion. Other points remain to be clarified: for example, plasma fibronectin binds to triple-helical or denatured collagen (Dessau *et al.* *Biochem. J.* 169, 55; 1978) whereas the isolated platelet protein apparently binds to collagen fibres but not to gelatin—that is, shows the same conformational specificity as for platelet-collagen interaction. Assuming that the findings and interpretations of Bensusan *et al.* are confirmed, however, more emphasis in future considerations of platelet-collagen interaction should be given to the mechanisms involved in fibronectin-collagen interaction. This has great significance in many cell adhesion phenomena apart from those involving platelets (Yamada & Olden *Nature* 275, 179; 1978). One quibble with Bensusan's paper, terminological rather than technical, concerns the use of the term 'receptor': as usually employed

J. L. Gordon is Principal Scientific Officer in the Cell Biology Department, ARC Institute of Animal Physiology, Babraham.

(for example in the context of cholergergic, aminergic and other sites) this implies a degree of specificity and affinity which is at variance with the characteristics of fibronectin in mediating interaction with collagen. This is, however, a small criticism of a paper that invites a major reassessment of attitudes in this field of research. □

Proposed optical Stern–Gerlach experiment

from Peter Knight

THE atomic beam work of Otto Stern and his colleagues in Hamburg was published in a series of papers bearing the subtitle 'Investigations with the Molecular Beam Method' (*Untersuchungen zur Molekularstrahlmethode*). The thirtieth and last, in 1933 by R. Frisch, reported the observation of the deflection of an atomic beam by the momentum carried by photons (*Z. Physik*, 86, 42; 1933); it closes with the remark: "It would certainly be possible to do more careful experiments. Unfortunately, for reasons beyond our control, the experiments had to be stopped prematurely". The phenomenon was revived by the work of Ashkin and his coworkers (most recently in *Phys. Rev. Lett.* 41, 1361; 1978) who demonstrated a large enhancement of the radiation pressure effect using laser radiation. Since then photon deflection has been discussed for atomic trapping and cooling, for spectroscopy and for laser isotope separation (although the latter now seems an outsider in the separation stakes).

A recent paper by R. J. Cook presents a new and quite simple analysis of atomic motion in a resonant laser electromagnetic field (*Phys. Rev. Lett.* 41, 1788; 1978). He shows how an atomic beam can be split by traversing an amplitude gradient of the resonant radiation in a fashion reminiscent of the old Stern–Gerlach demonstration of space quantisation. This splitting had been discussed earlier by Kazantsev (*Sov. Phys. JETP* 39, 784; 1974) and aspects of the subject reviewed by Stenholm (*Phys. Rept.* 43, 151; 1978). Photon deflection is produced by excitation and emission recoils, and by a force caused by the interaction of the induced dipole moment with the amplitude gradient of the radiation field. Cook's paper is concerned with the latter and his results are valid only if spontaneous emission can be neglected during the interaction time.

For an atom driven by a laser such that only two energy levels (with wave func-

Fig. 1 Focusing of atomic trajectories associated with the wavefunction u_- (Cook *op. cit.*)

tions c_1 and c_2) are relevant, the analysis is particularly simple. The Schrödinger equation for the time-dependent wavefunction for the atom interacting with an incident field leads directly to two uncoupled equations of motion for the symmetric ($u_- = 2^{-1}(c_1 + c_2)$) and anti-symmetric superposition ($u_+ = 2^{-1}(c_1 - c_2)$) of states. These two combinations represent special 'eigen-waves' for the atomic trajectories which propagate independently. An atom initially in its ground state is equally likely to be in one or the other of these superpositions. The 'eigen-waves' obey similar Schrödinger equations except that the potential energy for the u_+ is of opposite sign to that for u_- . The forces acting on atoms in the two waves are thus in opposite directions so that an amplitude gradient will split a collimated ground-state atomic beam into two components: an optical analogue of the Stern–Gerlach experiment. A well-collimated beam of atoms intersecting a Gaussian laser beam at right angles will see the optical beam as a cylindrical lens which focuses u_- waves but defocuses u_+ waves. (Fig. 1 shows the focused trajectory.)

Cook estimates that a 1 W laser beam focused to a 50 μm beam waist (with waist intensity about 10^4 W cm^{-2}) will act as a lens of focal length approximately 1 cm for an atom of slow thermal speed and typical mass and transition dipole moment. An atomic beam centrally traversing such a cylindrical 'radiation lens' would have a cross-section flux at the focus as shown in Fig. 2 where the u_+ wave has been deflected out of the

Fig. 2 Total atomic flux J at the focus of the 'radiation lens' for a centrally positioned beam of atoms, in units of laser beam radii (Cook *op. cit.*).

centre and the u_- wave focused.

The lens effect is an interesting demonstration of the inversion of our usual ideas. A lens is normally made of a medium (consisting of polarisable dipole oscillators) shaped so that a collimated light beam is focused by the density gradient of polarisability. Here we have a collimated atomic beam focused (or defocused) by polarisability effects in a light beam shaped to give an electric field gradient. Experimental investigation of these ideas does not seem too difficult and is presumably under way. □

Complexities of cultural evidence in the Lower and Middle Pleistocene

from John A. J. Gowlett

For many years the study of human evolution became, in the words of Irving Hallowell, 'more and more restricted to biological problems dealt with by physical anthropologists'. The cultural evidence, which is essential to a study of the distinctiveness of man, and which is mainly the province of the archaeologist, was scarcely considered as an aspect of biological evolution. The splitting of the study of early man into separate disciplines of archaeology, physical anthropology, and to some extent evolutionary biology, has its roots in the 19th century, and although much has been achieved in the way of interdisciplinary studies since Hallowell was writing, the central importance of the cultural evidence is still sometimes overlooked.

Archaeological work has however built up a record of behavioural complexity of a cultural nature going back at least 2 million years. Man can therefore investigate the evolution of his present cognitive capacity through the permanence of the cultural record. Considering the clear evidence of humanity that is available, it is surprising first that philosophers have made

J. A. J. Gowlett is in the Department of Archaeology, University of Cambridge.

P. Knight is SRC Advanced Fellow in the Department of Physics, Royal Holloway College, University of London.

so little adjustment to this long time-scale, and second that animals other than man are so often used inappropriately as models for human evolution.

Most of the earliest archaeological evidence comes in the form of stone implements, and although these convey much more information when found in context than in isolation, their study is still an important part of Palaeolithic archaeology: they do, after all, fall clearly within the domain of culture, indicating not only the regular transmission of ideas as learned behaviour, but also the 'imposition of arbitrary form on the environment'. In this sense, Holloway has suggested the potential of the artefacts as a behavioural or sociopsychological record, whereas archaeologists have often been more concerned with classification and typology. Even within the Lower Pleistocene period, which as now defined lasts from ~1.8 down to 0.7 Myr ago, stone-working exhibits design regularities, indicating consistent linkages of ideas (and thus allowing typological description: Fig. 1)^{3,4}. In archaeological terminology, the artefacts which a group of prehistoric people 'manufactured in one area over some span of time' form an 'Industry', but in practice the major taxonomic entities of the Lower Palaeolithic are 'Industrial Complexes' or 'Traditions', defined as groupings of Industries 'considered to represent parts of the same whole'. The vagueness of this definition is of limited importance for descriptive purposes as in the Lower Pleistocene only two industrial traditions of stone-working are generally recognised: the Oldowan, known almost entirely from Africa, and the Acheulean, which continues through the Middle Pleistocene, becoming widespread in the Old World.

The Oldowan, which has an approximate age range of 1.8–1.6 Myr at Olduvai Gorge in Tanzania^{5,6}, is characterised by the regular practice of simple flaking, and the production of a range of tool forms, often based on cobbles. Among these, the discoids and choppers show bifacial working: the production of a resolved edge through flaking from both sides, a complex process involving both feed-forward and feedback. Industries from East Turkana⁷ and the Omo⁸, aged about 2 million years, can be ascribed to the Oldowan, but show some differences which may be accounted for partly by differences of raw material. A variant defined as the 'Developed Oldowan' by Mary Leakey succeeds the Oldowan at Olduvai, having a range of ~1.6–1.2 Myr, and reappearing according to her in higher beds dated to ~0.8 Myr. The Developed Oldowan has a slightly wider range of tool forms, with more em-

phasis on bifacial working, including some 'poorly made and generally small bifaces' at Olduvai. The Karari Industry from East Turkana⁹, an industry from Chesowanja in Kenya¹⁰ (both probably aged ~1.5 Myr) and an industry from Gadeb¹¹ in Ethiopia have all been described at least provisionally as variants of the Developed Oldowan, demonstrating the usefulness of this term as a descriptive label.

The Acheulean Tradition continues with most of the Oldowan forms, but introduces a new elaborate conjunction of ideas, in the working of bifaces with a well-defined long axis, made on blanks which are specially struck long

flakes (Fig. 2). The bifacial working clearly was a precondition for this development, but it is not clear whether or not the ideas of a long axis and lateral symmetry preceded the use of long flakes. This point has a relevance to the difficulties which archaeologists find in relating the Developed Oldowan and the Acheulean, which are sometimes contemporary, for the Acheulean is first found within the time range ~1.4–1.3 Myr at Olduvai site EF-HR, and Peninj site RHS, also in Tanzania¹². Few other Lower Pleistocene Acheulean sites are known—among these are the Olduvai Bed IV sites, almost certainly the large site

complex at Kilombe, Kenya¹³, and perhaps Kariandusi—although in the Middle Pleistocene Acheulean sites are very common. The Developed Oldowan and the Acheulean have been interpreted at Olduvai as separate cultural traditions, with the suggestion that different hominid groups were involved as makers. Such ideas have, however, been offered only as possibilities, and with very careful qualification^{3,6}, but the existence of two or more hominid species at least in the earlier Pleistocene now seems incontrovertible. In Olduvai Bed I a robust Australopithecine (*A. boisei*) and *Homo habilis* were both found in association with Oldowan artefacts. From both Olduvai Bed II and from East Turkana there is convincing evidence that *A. boisei* and *H. erectus* existed as contemporaries in the period ~1.5–1.3 Myr. At Chesowanja, finds made in 1969 of *A. boisei* were close to recent excavations where artefacts have been found *in situ*¹⁴.

At present neither the palaeontological nor archaeological evidence seems likely to show whether in fact more than one hominid species made stone tools, but Holloway's work on cranial endocasts of fossil hominids does indicate that the brain organisation of various Plio-Pleistocene hominids, including the Australopithecines, was basically human-like rather than ape-like¹⁵. As other assessments of what is 'advanced' in a hominid are largely subjective, it must be recognised that we have no *a priori* grounds for saying that any of these hominids did not make artefacts.

This issue is an important one in the study of human evolution, and needs to be faced openly, but it is not necessary to demand immediate answers, and indeed the growing emphasis on contextual studies encourages other lines of approach. It may be observed that the current definition of 'Industrial Complex' allows use either in a simple descriptive sense, or in a more specific sense of cultural entity, whereas the artefact record in the Lower and Middle Pleistocene, seen in general, shows much continuity of ideas (Fig. 1) coupled with much variability in detail. Some of this variability, which occurs in size, morphology, and proportional frequencies, can be explained by factors such as (1) short-term stylistic change; (2) activity variants, where a human group might use specialised tool kits for individual tasks¹⁶; (3) raw materials, the form and fracture properties of which might influence the end-product; and (4) random or stochastic variation¹⁷. In contrast, remarkably high levels of standardisation are sometimes achieved at a particular locality, implying strict controls. Such combinations of flexibility and stability may reflect the essential adaptive

Fig. 2 A simplified diagram of the complex pattern of biface manufacture encountered on Lower and Middle Pleistocene Acheulean sites. Operated as a multi-stage process with geographic separation of stages, it is powerful evidence for organised forward planning, and metrical data provide evidence for remarkable levels of control.

advantages of culturally controlled behaviour. Terms like Oldowan and Acheulean lay stress on selected continuities, and unless used purely descriptively may eventually prove too rigid to embrace the complexities of the archaeological material.

The contextual evidence helps to illustrate this complexity. Even in the Oldowan, artefacts were transported to site, sometimes several kilometres from the source rock, and careful selection of raw material is apparent. In the Acheulean the process is much more complicated and given the distances of transport, and quantities of material, it is interesting for what it can tell us about goal-seeking behaviour, forward planning, habitual and systematic exploitation of an environment, and cognitive mapping of that environment. A great deal can thus be gained from the study of sites in relation to the sediments that contain them. In general sampling density is very low because of the great timespans, and coupled with the high sample variability presents 'in methodological terms... a tough situation'¹⁸. Isaac has treated the background to this in papers which make an important contribution to theory¹⁹. Certain exceptional experimental circumstances, with for example high densities of sites in continuous sediments (such as Olorgesailie or Kilombe), or with sediments extensive over many square kilometres (such as at East Turkana)¹⁹ allow tests which may give some firm answers about the nature of variability in controlled spans of space and time.

In spite of limitations imposed through poor time calibration within sequences, and biases from non-random patterns of exposure, such experiments can work on the density and spatial distribution of occupation traces, and when linked with studies of the transport of raw materials, suggests a whole range of research possibilities touching on factors of interest such as group size, territoriality, and localised or seasonal adaptations.

To further such work, much more archaeological fieldwork is needed, as the corpus of 'routine' finds is very small by the standards of other areas of archaeology, and as only through such work will exceptional finds of unexpected nature crop up from time to time.

It is, unfortunately, too easy for a dogma to arise about future research objectives and methods of working. In the past few years, the exploration of certain extensive areas of sediments, belonging especially to the time-span 3–1 Myr, has dictated the terms of 'palaeoanthropological' research, and led to a particular interdisciplinary balance, which relates mainly to work in the field. Judging from past experience, it cannot be assumed that these approaches will be maintained unaltered in the future. The 'environmental paradigm' though indispensable, forms only one segment in the possible range of approaches: in human evolution, the study of human intellectual development is clearly no less important than that of 'origins', and the potential for cooperation between, for

example, workers in archaeology, hominid neurology, and psychology, is already becoming apparent, although it can hardly happen in the field. To set this subject matter within the context of work in the philosophy of science is also desirable, for the archaeological record has a potential for broadening time-perspectives, and perhaps significant contributions to make towards studies of the phenomenon of consciousness or self-awareness.

Relativistic nuclear collisions

from A. M. Poskanzer

In the past few years the Bevalac Accelerator at Berkeley has allowed the study of collisions of nuclei at energies which before were accessible only with cosmic rays. The maximum energy attainable, 2 GeV per nucleon, is two orders of magnitude higher than was previously available in the laboratory. At present, beams as heavy as ⁴⁰Ar are in use, but a 2-year improvement project has started which will allow acceleration of beams up to uranium. The construction of similar relativistic heavy ion accelerators has been proposed in West Germany, Russia, and Japan.

The main goal of studies of relativistic nuclear collisions is to make nuclear matter at high density and temperature, with the aim of studying the equation of state of nuclear matter. A sketch of the theoretical binding energy of nuclear matter as a function of density is shown in the figure; the derivative of this curve with respect to density is the equation of state. What is known experimentally about nuclear matter at present is one point on the graph; the equilibrium density of nuclei, and the binding energy of nuclear matter at this density. Also, we know that at this point there is a minimum, which is to say, nuclei are bound. Even the curvature at this

Fig. 1 (From Poskanzer *Comm. Nucl. & Particle Phys.* 7, 41; 1977).

point, that is, the compressibility, is poorly known experimentally. The various curves are some of the speculations about what might happen at high density. At still higher densities it is possible that the nucleons might break up into their constituents to produce quark matter.

It is clear that the first requirement for making nuclear matter at high density and temperature is to collide a high energy heavy projectile at small impact parameter on a heavy target. Goldhaber (*Nature* 275, 114; 1978) estimates that densities of four to ten times normal nuclear density could be achieved in collisions on uranium nuclei with uranium ions of 2 to 8 GeV per nucleon. Thus, in a system containing almost 500 nucleons, one may produce both matter and energy

densities far in excess of any previously attained in a volume of nuclear size.

However, research proceeds in smaller steps for practical reasons and the first results on central collisions were for 250 and 400 MeV per nucleon ²⁰Ne ions on a uranium target (Gosset *et al.* *Phys. Rev. C* 16, 629; 1977). These results, on the energy spectra of protons and light nuclei emitted in the reactions, generated enormous interest, and by now have been fitted by 20 groups of researchers using 12 distinct models. The extreme disparity in the bases of these models is best typified by comparing the fireball model, a so-called thermal model, to the intranuclear cascade model. In the nuclear fireball model one assumes a clean-cut geometry which divides the nucleons into spectators and participants, and then that the participants achieve thermal equilibrium before separating. In the cascade model the two-body collisions of all the constituents are followed. The aim in these model calculations has been to describe the 'background' physics of what goes on, so that one could search for interesting new effects. In the metaphor of the Berkeley Summer Studies, the models are tools for cutting through the weeds to look for the flowers. The amazing thing is that, within factors of two, most of the models were able to fit the data. It was thought that energy and momentum conservation together with a spectator-participant concept, constrains the models so that differentiating between them must await more accurate and extensive data. However, let us examine another possible explanation.

The most recent publication of a calculation is by J. D. Stevenson (*Phys. Rev. Lett.* 41, 1702; 1978). It contains results from one of the five intranuclear cascade calculations which are in progress. Because of the reasonable fit obtained he concludes that "this calculation shows that the radical assumption that a hot nuclear fireball is formed in nucleus-nucleus collisions is not necessary to explain existing experimental results." On the other hand, he also shows that the average emitted nucleon has undergone five to six scatterings and quotes results from gas studies to the effect that this is more than enough to show equilibrium features. Thus, it appears that Stevenson has shown microscopically that there is some justification to the macroscopic thermal models. He has possibly also given another explanation of why most of the model calculations agree: the large degree of thermalisation obscures the initial assumptions of the models. The significance of this point buried in Stevenson's article is not trivial. Although one can follow collective motion microscopically, macroscopic models are enormously simpler, and

A. M. Poskanzer is Scientific Director of the Bevalac at the Lawrence Berkeley Laboratory, Berkeley, California.

much more easily relate effects to observations. In addition, all the interesting effects we are looking for are macroscopic effects. Classical microscopic calculations, like the one by Stevenson, are useful in testing model assumptions, such as the degree of thermal equilibration, but provide little insight into the collective properties of hundreds of nucleons. We need macroscopic models characterised by a few bulk parameters, such as the compressibility modulus, which are adjusted to experimental data in order to learn new physics. For instance, for compression and re-expansion effects, some macroscopic calculations have just recently pointed out the effects which might be seen experimentally.

The data fitted by Stevenson were taken with a detector of small solid angle so that the experiment looked at only one particle from each event but accumulated data for many events. However, present experiments measure the multiplicity of charged particles associated with the particle in the main detector, and thus are able to select central collisions on the basis of their high multiplicities. Experiments that measure two particles in each event are in their early stages. These two-particle correlation studies will give a much better indication of the degree of thermalisation, because in a single nucleon-nucleon scattering the two nucleons tend to be correlated at 180° in the centre of mass, while in a thermal model they would be uncorrelated. The future lies in measuring as many of the final particles as possible in each event and thus determining the collective motion of the nucleons emitted. One hopes that one day it will be possible to relate data of this kind back to the equation of state of the compressed nuclear matter. □

Insects need cilia

from Michael Sleight

It is generally agreed that arthropods lack water-propelling ciliary organelles of the 9+2 pattern, except on the sperm of some members of the group. Recent observations by Bradley and Satir (*J. Cell Sci.* **35**, 165; 1979) suggest that insects have found it necessary to develop alternative structures to perform the function of fluid propulsion or at least the transport of uric acid crystals, in the Malpighian tubules. The authors have named these structures axopods, by analogy with the stiff microtubule-supported pseudopodia of the Heliozoa and Radiolaria.

The axopods found in the lumen of

Malpighian tubules of the bug *Rhodnius* are branching projections occurring among, but longer than, the microvilli of the cells lining the lower tubule; they contain between 1 and about 50 microtubules and vary in thickness between about 0.2 and 0.8 μm . The microtubules are separate and regularly spaced, several diameters apart, but without any of the specific patterns or links found in protozoan axopods (Cachon & Cachon *Ann. Biol.* **13**, 523; 1974). Where the insect axopods branch, groups of microtubules separate and pass into each section. At the base of the axopod the microtubules extend deep into the cell to end near an inner cell boundary or in a cluster of mitochondria; no association has been found with a centriole or other microtubule-organising centre. Sections of the axopods reveal groups of longitudinal microfilaments close to the peripheral membrane.

It has not been possible to gain a clear view of the insect axopods in motion, but the movement of uric-acid crystals is consistent with propulsion by the axopods, and no other means of propulsion appear to be present in the experimental situation. The propulsive action is assumed to take the form of active lashing of the axopods. Analogous microtubular organelles other than cilia and flagella do not normally show this form of motion; the straight axopods of *Heliozoa* merely change their length to promote cell movement (Waters *J. Cell Sci.* **3**, 231; 1968) and the haptonemata of certain flagellates, flagellum-like projections that contain a small number of single microtubules, perform coiling movements (Leadbeater *J. mar. biol. Ass. U.K.* **51**, 207; 1971). The appendages of the marine protozoan *Sticholonche* may come nearest to insect axopods, for the numerous, stiff, microtubular exopods of *Sticholonche* are pivoted at the base and are caused to perform rowing motions by the contraction of (non-actin) microfilaments attached to their bases (Cachon, Cachon, Tilney & Tilney, *J. Cell Biol.* **72**, 314; 1977). It seems likely that microvilli of insect malpighian tubules may have been invaded by microtubules; while these provide the stiffness necessary for the propulsion of fluid, the actual bending forces may be provided by microfilaments, as Bradley and Satir suggest. Fluid propulsion of a similar type has been observed in a number of other situations in arthropods; it will be interesting if similar forms of modified microvilli have been adopted elsewhere or whether true cilia do exist on epithelial cells of arthropods. □

Michael Sleight is Professor of Biology at the University of Southampton.

A hundred years ago

OUR readers may remember that early in the year General de Nansouty, the hardy director of the Pic du Midi Meteorological Observatory, was cut off from communication with the world below, the severe weather having so affected the telegraph as to prevent it from acting. Fears were entertained for the General's safety, and M. Albert Tissandier resolved to organise a party for the ascent of the Pic and the succour of the veteran observer. An interesting account of this ascent appears in *La Nature*, to which we are indebted for the accompanying illustrations. The snow-storm having somewhat abated at Bagnères-de-Bigorre on January 9, M. Tissandier resolved to attempt the Pic next day, in company with three of General Nansouty's usual guides.

They set out at 9 A.M. on the 10th, and in spite of the deep snow and fallen avalanches, the ascent was at first not difficult. After equipping themselves for snow work at some huts occupied only in summer, the ascent was begun in earnest. The weather was grey and uncertain, the temperature 0°Cent. , with a thick mist that prevented anything being seen beyond 300 metres. The snow became deeper and deeper as they advanced, and one of the guides went before to show the way, the others following the marks of his footsteps up the steep slope of the mountain side. Sometimes they were buried to the waist, and often they had to rest to recover breath.

review article

Nerves and genes

William G. Quinn & James L. Gould

Department of Biology, Princeton University, Princeton, New Jersey 08540

Work with single-gene mutations in a variety of organisms is yielding insights on how genes build nerve cells and specify the neural circuits which underlie behaviour.

It is the business of scientists to explain away the magic in the world. The largest coherent body of magic remaining is the behaviour of men and animals. Behavioural geneticists try to construct plausible explanations for behaviour patterns by studying genetic variants. Historically, they have sought to compare inbred strains, or to cross them and examine the progeny¹. Such comparisons inevitably involve many genetic differences, making the results virtually impossible to interpret. A more recent approach initiated by Delbruck and Benzer has been to generate single-gene mutations which affect behaviour, to analyse the mutants, and to try to infer general principles about how normal behaviour is created. One advantage of such single-gene changes is that now behavioural patterns can be dissected into their component parts. This genetic extension of traditional ethology should have something important to say about how behaviour is organised and regulated, and has been reviewed recently². A more ambitious and potentially more powerful strategy is to examine the effects of single-gene mutations on the ultimate common denominator of behaviour—the physiology of nerve cells and the wiring patterns of neural circuits. This review traces the recent progress of this approach, selecting the work which seems to offer the best prospects for the future.

Single cell physiology

The underlying mechanism for neural activity is ionic. Typically, a metabolically dependent ion pump moves Na^+ out of and K^+ into the neurone, creating a steady potential difference across the membrane. In an action potential, depolarising the cell membrane beyond a threshold voltage opens channels in the membrane specific to each ion, the sodium channel opening and closing more rapidly than the potassium channel. The resulting large change in membrane potential depolarises nearby patches of membrane, allowing the propagation of the impulse through the cell. When the action potential reaches a presynaptic terminal, Ca^{2+} enters through its own channels, causing the release of chemical transmitters which diffuse across the synaptic junction to the next cell, opening still another class of ion channels in the next cell, and thus continuing transmission of the electrochemical signal.

The elucidation of this picture, and the explanation of most of the cell's electrical properties in terms of a few ionic conductance changes, is the major triumph of neurobiology in the last half-century. A substantial problem remaining for neurobiologists is to understand the molecular operation of the various ion channels (presumably proteins) in the neuronal membrane. Two organisms have been found in which the channels can be altered by mutation.

Paramecium

Although unicellular, *Paramecium* behaves as if it were rational. Ordinarily, it propels itself forward through the water by the coordinated beating of cilia distributed over its exterior. However, if it swims into a physical barrier or a noxious chemical, it quickly reverses the direction of its ciliary beat, swims backwards for a time, then sets off in a new direction³. The simultaneous reversal of all the cilia suggests an electrical basis for the behaviour, and experiment bears this out. It is possible to record intracellularly from *Paramecium*, and observe an extraordinary repertoire of ion conductance changes⁴. These can best be understood by following events during an avoidance reaction.

Mechanically stimulating the front of the animal (mimicking collision with a barrier) depolarises the membrane, probably by local influx of sodium ions. This depolarisation spreads throughout the cell by passive current flow and raises the membrane potential above threshold. At this point, a separate, calcium conductance channel is activated, and several regenerative action potentials occur, based on calcium influx. The increased Ca^{2+} concentration inside the cell somehow changes the pattern of ciliary beating⁵, reversing the direction of power strokes so the *Paramecium* backs up. After 1–5 s, the calcium level in the cell decreases (presumably by active ion pumping) and the animal resumes forward swimming.

This fixed action pattern involves relatively few events, and at least two of them are ion conductance changes. Therefore, one can screen for behavioural mutants in *Paramecium* with the hope that some will have altered channels. Using ingenious selection techniques, Kung *et al.* have found many abnormal behaviour patterns⁶. Two are especially dramatic: *pawn* mutants, like chess pawns, cannot back up. This is because their membranes will not produce calcium spikes even when depolarised far above normal threshold. Apparently, *pawn* mutants lack the normal voltage-dependent calcium conductance channels. The *paranoliac* mutant, on the other hand, shows bouts of reverse swimming whether it encounters noxious stimuli or not. Electrophysiology shows that *paranoliac* mutants have normal sensory generator potential and calcium spike initiation, but are blocked in membrane repolarisation after the action potential⁷. Instead of a series of spikes, they show a long, flat peak. This abnormality of *paranoliac* is expressed only in the presence of external sodium⁸. The membrane component affected by *paranoliac* mutations remains unknown. However, radioactive tracer studies indicate that the depolarised membrane in the mutant becomes abnormally conductive to many ions, including calcium, which explains the long periods of ciliary reversal⁹.

So far so good. The visible behaviour of *Paramecium* is closely correlated with the electrical properties of its membrane, and some behavioural mutations affect ion conductances in an apparently straightforward manner. Sophisticated electrophysiological experiments are feasible, such as clamping the membrane voltage quickly to a new level and watching the kinetics of conductance changes. Oertel *et al.*¹⁰ built such a voltage clamp and compared *pawn* mutants (which have no calcium spikes) with normal *paramecia*; thus, they were able to measure the conductance changes specifically attributable to the calcium channels. One could hope to do similar voltage clamp studies with 'leaky' *pawn* mutations which do not completely abolish calcium conductance, compare the kinetics of calcium conductance changes in normal and mutant individuals, and try to gain some insight into the mechanism of voltage-dependent channel activation and inactivation (gating).

Prospects for chemically isolating the channel proteins also look good. The lipid membrane which sheaths each cilium is continuous with the plasma membrane of the cell. When treated with agents such as chloral hydrate, the cilia become stiff and break off from the cells; they can be isolated and membrane fractions purified from them using conventional biochemical methods¹¹. The calcium channels, at least, are concentrated in the ciliary membrane (de-ciliated *paramecia* show no calcium spikes^{12,13}). This raises the possibility of finding altered membrane proteins in *pawn* mutants, then examining the chemical alterations in the mutant channel. Explaining ion channels and gating in chemical terms is a serious problem; *Paramecium* seems a logical place to try.

However, the behaviour of *Paramecium* is much more complicated than the outline above suggests. An increasing variety of unexplained behavioural mutants (spinners, sluggishes, staccatos) have been isolated. Detailed electrophysiology shows a correspondingly bewildering array of ion conductance channels in the cell membrane. It is as if *Paramecium* tried to compact all the functions of a nervous system into one cell.

These eccentricities of *Paramecium* do not detract from its real promise. Voltage-dependent calcium channels are present in the ciliary membrane. It is a matter of time before the channel proteins, apparently specified by the *pawn* genes, are chemically isolated. *Paramecium* is the one system where electrophysiology, membrane chemistry and genetics can all be directly applied to find out what a conductance channel looks like and how it opens and closes.

Drosophila

At first glance the fruit fly seems unpromising for neurophysiological studies: most of its 10^5 neurones are very small ($<5\ \mu\text{m}$); they interact in a tangle of neuropil, and they receive their oxygen supply through tracheoles, making respiration of the preparation a problem. These difficulties limited the success of the earliest studies on adult mutants by Ikeda *et al.*¹⁴⁻¹⁷. They were overcome by the inspired naivete of L. Y. Jan, Y. N. Jan and W. A. Harris, who simply slit third-instar larvae down their backs and pinned them out with the nervous system and ventral muscles exposed. The muscle fibres in two longitudinal cords are wide, flat and easy to record from, and the motor nerves can be cut and stimulated directly with a suction electrode. Using this system, Jan and Jan have worked out the bases of the muscle resting and synaptic reversal potentials, identified L-glutamate as the probable transmitter^{18,19}, and shown that in low calcium solutions neuromuscular transmission in *Drosophila*, like that of the frog²⁰, is quantal, each unit of postsynaptic excitation presumably being caused by the release of transmitter from one synaptic vesicle. Thus, given a mutation affecting synaptic transmission, they could determine if the abnormality was presynaptic (affecting the number of quanta released) or postsynaptic (affecting responsiveness to transmitter and hence the apparent size of quanta). Such analysis also allows the detailed kinetics of transmitter release to be followed.

Screening of previously isolated mutations which affect whole-fly behaviour revealed one in which the larval neuromuscular preparation was also altered. Flies carrying a *shaker* mutation²¹ show spontaneous rhythmic leg movement under anaesthesia. Larval neuromuscular transmission is relatively normal in physiological conditions but becomes obviously different in low calcium solution. Paradoxically, it shows greater synaptic efficacy, with more transmitter released over a longer time course. Jan *et al.*²², applying classical physiological techniques, showed that the abnormality in *shaker* is presynaptic. Conductance to calcium was prolonged up to 1 s after stimulation of the mutant nerve terminal. Apparently, the calcium channels in the mutant open normally but are slow to close, so that calcium continues to enter the presynaptic terminal, causing greatly increased vesicle fusion and transmitter release.

It is then natural to wonder whether the abnormality is in the calcium channels themselves or in the action potential which causes them to open. In fact, the action potential is abnormal in the mutant. Normal synapses can be made to behave like *shaker* mutant synapses by applying tetraethylammonium or 4-aminopyridine, drugs which block potassium conductance. Furthermore, extracellular recording shows electrical activity in the mutant motor nerve which persists after stimulation has ceased (Jan, Jan and Wu, unpublished data). All this indicates that the *shaker* mutation blocks potassium channels in the motor neurone, so the voltage-dependent increase in potassium conductance which repolarises the nerve after an action potential²³ never occurs. Extended depolarisation of the nerve then leads to prolonged calcium conductance and enhanced vesicle release at the terminals.

This experimental success stimulated a direct search in Benzer's laboratory for new physiological mutations, specifically temperature-sensitive paralytics which affect larvae as well as adults. One such mutant, *nap*, was found²⁴. Its name describes both its outward appearance (torpor) and its physiological abnormality (no action potential) at 35 °C. Motor nerves in mutant larvae fail to conduct action potentials at this elevated temperature, whereas those of normal larvae are unaffected. Most probably, the mutant gene specifies voltage-dependent sodium channels, which become blocked at high temperature.

If the above arguments are true, then mutants are available in *Drosophila* which affect the two conductances classically defined by Hodgkin and Huxley: *shaker* blocks g_K while *nap* blocks g_{Na} at high temperature. We are left with the problem of what to do with the mutants. It would be impossible to voltage clamp a mutant motor nerve to measure conductance kinetics directly, although it may be worthwhile to search for larger neurones in the fly which are similarly affected. Prospects for biochemical studies with the mutants also look intimidating. Nevertheless, if one set out to apply genetics to the phenomena underlying the Hodgkin-Huxley model—ion selectivity and voltage-dependent conductance changes—one could not hope for a better start.

A less easily explained physiological mutant, the *bang sensitive* (*bas*) fly, has been found in several laboratories^{25,26}. These mutants pass out for several seconds after mechanical shock, as when their culture vials are rapped on a table. Jan and Jan²⁷ discovered that one of these, *bas*^{MW1}, is specifically enhanced in long-term facilitation at the larval neuromuscular junction. Long-term facilitation, sometimes called post-tetanic potentiation, means increased synaptic efficacy after a train of repetitive stimuli. It is phenomenologically similar to ordinary (short-term) facilitation, except that the amount of pretreatment stimulation required for its onset is greater and it lasts longer. The two processes can now be formally distinguished using mutations: *bas*^{MW1} enhances only long-term facilitation, whereas *shaker* specifically increases short-term facilitation. In *bas*^{MW1}, long-term facilitation requires sodium (but not calcium) influx to the presynaptic terminal during the pretreatment period. The increased synaptic efficacy after pretreatment is due to a prolonged period of calcium conductance in the terminal after each stimulus. How a rise in intracellular sodium might

induce the calcium gates to remain open is not understood. Whether other ion channels are affected is not known.

Normal flies (and other invertebrates²⁸) show long-term facilitation like *bas^{MW1}*, although they require longer and more intense pretreatment stimulation. Also, the physiological properties of *bas^{MW1}* can be mimicked by treating a normal neuromuscular preparation with ouabain, an inhibitor of the sodium-potassium pump. This suggests that the *bas^{MW1}* mutation may simply reduce the efficiency of the pump. Alternatively, it could accentuate the mysterious process by which intracellular sodium leads to facilitation.

Neural circuits

The behaviour of multicellular animals is the result of interactions between nerves. Conceptually at least, the question of how nerves combine to produce behaviour may be broken down into two parts: how nerve circuits work, and how these circuits come to be appropriately wired during development. In reality, however, the study of circuitry inevitably leads to questions of neural development and specificity. This is because mutations affecting wiring usually begin to act during development. As a result, genetic studies of nerve interactions which have proceeded beyond the level of drawing the circuit diagrams—no mean task in itself—have either evolved into studies of development or abandoned the 'genetic lesion' technique for the laser-beam scalpel, or both.

Mapping *per se* is an attempt to define which cells are connected to which, and to characterise the anatomical interactions as strong or weak, electrical or chemical, inhibitory or excitatory, and so on. Direct physiological confirmation of these descriptions has rarely been possible, however, for reasons encapsulated in Gould's corollary of Quinn's law. Quinn's law states that the convenience of genetics multiplied by the quality of the behavioural repertoire is a constant for all animals. Hence, bacteria have superb genetics and marginal behaviour, while undergraduates have very interesting behaviour but cumbersome genetics. Gould's corollary states that the quality of the genetics multiplied by the ease with which single nerve cells can be identified and penetrated is also a constant.

However, mapping of isogenic organisms has produced one very encouraging general result: the overall pattern of wiring—which nerve cells are connected to which—is found to be remarkably constant from one animal to the next, whereas the details of the wiring—the specific number and anatomical location of the connections—are quite variable. As the same genes produce the same behaviour against a background of synaptic and dendritic variability, the hyper-fine structure of neural wiring can reasonably (and fortunately) be ignored²⁹.

Nematode nervous system

The most ambitious attack on the genetic control of neural wiring is being made in Brenner's laboratory with the nematode *C. elegans*. This millimetre-long creature has 'good' genetics³⁰, compensatingly simple taxis behaviour³¹⁻³³, and a seductively finite 258 nerve cells. Intuitively, it seems possible to map all the nerves and look for general principles of circuitry. Goldschmidt had the same idea 70 years ago, and mapped the large nematode *Ascaris* using serial sections and a light microscope³⁴. Brenner *et al.* have mapped most of *C. elegans* using an electron microscope, 20,000 serial sections per nematode, a computer, and much persistence^{35,36}. In nearly all respects, *C. elegans* is found to be a miniature *Ascaris*.

Conceptually, the nematode nervous system is divisible into four parts: the head, which contains virtually all the sensory apparatus; the pharynx, which mediates ingestion; the nerve ring or 'brain' in the neck; and everything further back. The muscle system can be classified along the same lines: the head muscles, which aim the head; the pharynx muscles, which manipulate and pump food; the neck muscles, which help aim the head and aid in swimming; and the rest of the body, which swims.

The 50 or so nerves in the head have been mapped and guesses have been made about their functions. Specific chemotaxis and tactile mutants have been created which display variable anatomical aberrations at least roughly corresponding to these guesses³⁵. However, the incomplete penetrance and pleiotropic nature of these sensory mutations is frustrating.

There are about 20 nerves in the pharynx—sensory cells, interneurons, motor neurones, and multi-functional cells which seem to act as both mechanoreceptors and motor neurones. These have been sorted into a hypothetical but plausible circuit with typical ethological releaser and fixed-action pattern units³⁷. The present impossibility of doing electrophysiology on this animal and the lethal nature of defects in a feeding circuit make analysis difficult.

The 200 or so nerves which interact in the nerve ring create a maze so complex that little can be said about them except that the sensory nerves from the head as well as the head and neck muscles go into it, and the interneurons which control the ventral cord come out of it³⁸.

Fig. 1 Schematic representation of post-embryonic development of cells in a portion of the nematode ventral nerve cord, showing patterned divisions from a single precursor cell P12. Cells a-e exemplify five anatomical classes of neurones present in the mature animal; S₁, S₂ are somatic cells; X indicates cell death.

The rest of the nematode, although long ignored, has turned out to be by far the most rewarding to study. The nerve ring sends out a ventral cord which runs the entire length of the animal and contains about 60 motor neurones. Muscles in the ventral half of the body send processes to the ventral cord. The dorsal cord, which services the muscles in the dorsal half, is discontinuous, being made of pieces sent up from the ventral cord³⁹.

A closer look reveals that this swimming motor system consists of 12 almost identical wiring groups in tandem, each with five classes of cell. Developmental studies^{40,41} indicate that these groups arise from 12 precursor cells which divide several times each (Fig. 1). The pattern of division and specialisation is intriguing. After a division, the posterior daughter cell is almost always more like the parent than the anterior cell, and is also more likely to be programmed to die. Relative position may be the crucial cue for nematode differentiation. Although the different groups retain different classes of cells, the same pattern of division is always followed (Fig. 1). For example, although in all female *C. elegans* cell c dies, it is always necessary to make cell c so that its sister can go on to divide into cells a and b. More remarkably, in two of the groups, cell b is also necessarily made and killed so as to produce a cell a (Fig. 1).

Again, the wiring diagram leads immediately to speculation about how the circuit works. Cells a and b look like antagonists, one (who knows which) excitatory, the other inhibitory. Cell d might be responsible for the deep ventral bend which seems

R404

necessary to reverse direction. Cell *e* is perhaps part of a reciprocal inhibition system used to coordinate movement. If these guesses are correct, then *C. elegans* swimming, like the flight of many insects, is myogenic, confirming an earlier and equally elegant behavioural analysis⁴².

C. elegans, quite unexpectedly, has been found to be a very useful animal for developmental studies. It is possible in principle to establish the lineages of all its cells, and this has already been done for 180 of its 550 embryonic cells⁴³. Post-embryonically, new neurones are formed (Fig. 1) and some old ones undergo remodelling⁴⁴. In larvae, class *d* cells innervate only the ventral muscles, whereas in adults they innervate only dorsal muscles. A study with mutants⁴⁴ sheds some light on the general rules of neural development in *C. elegans*. One mutant lacks all the late-developing motor neurones. These are the only cells which innervate the class *d* nerves. Nevertheless, the *d* cells rewire themselves as usual even in the absence both of normal input from the neurones which drive it and of others which take over its connections to the ventral muscles. In *C. elegans*, at least, no synaptic input is necessary to make, break and remake normal synaptic output connections. Unfortunately, the reverse is true of other animals, especially mammals. In any case, despite a limited behavioural repertoire and the impracticability of physiological confirmation, nematodes are providing fascinating information about neural development.

At this stage the same questions might be answered by laser-beam lesions rather than mutations, but the ultimate power of mutant analysis is clear. For example, a mutation has recently been found which rearranges the pedigree of developing nerve cord cells, and another interferes with the cell divisions shown in Fig. 1, producing multinucleate neurones with strikingly novel morphology (H. R. Horvitz, personal communication).

Songs and sensory circuits of insects

Most of the *Drosophila* nervous system is quite complex, and neural analysis of behaviour patterns is slowly progressing from the outside of the animal in. For example, courting males sing a species-specific 'love song' by extending and vibrating their wings towards females⁴⁵. The circuits underlying this behaviour can be dissected with gynandromorphs—animals which are part male and part female. Flies with male heads and female bodies will extend their wings to females as if in courtship, so apparently the 'will' to begin the song is located in the brain⁴⁶⁻⁴⁸. However, the fly goes on to produce a proper *Drosophila* song only if there is some male tissue in the thorax as well; the actual pattern-generating circuit is probably located in the thoracic ganglion. This parallels the situation in crickets, where males with specific brain lesions are normally incapable of song production, although a headless cricket body will produce a complete song if the thoracic ganglion is stimulated⁴⁹. In both species, the decision to sing and the actual song pattern are mediated by separate neural structures. Other experiments with hybrid crickets⁵⁰ suggest that the male circuit which generates the courtship song pattern is specified by the same genes as the female circuit which recognises the song (they may even be the same circuit).

Crickets have also been used to study neural development. One single-gene mutation causes the loss of the mechanoreceptive filiform hairs on the cricket cerci⁵¹. As a result, the mutant shows no sensitivity to touch on the cerci. The sensory nerves from the missing hairs are completely normal, but the large interneurone to which they project is 'withered'. Apparently, normal stimulation is unnecessary for the maintenance of receptor cells, but is crucial for the integrator cell. This has striking parallels in mammalian visual development. In cats, for example, failure to see out of one eye during a critical period leaves the receptor unaffected, but prevents the normal development of the visual cortex, causing irreversible blindness in one eye⁵². We would like to believe that there is a general principle of neural organisation here somewhere, and the dis-

covery that cricket cerci have a critical period makes that possibility more likely⁵³. If one cercus is waxed over for a time early in development so that the hairs cannot be stimulated, the animal becomes deaf on that side. Removal of the wax has no effect.

Mouse mutants

Mouse brains, although small and unintelligent, are organised like ours and thus allow investigation by conventional neuroanatomical, histological and physiological techniques. Moreover, large areas of the mammalian brain, such as the cerebellum and visual striate cortex, are composed of similar circuit elements repeated over the surface of the brain^{54,55}; one can therefore study a small patch of neural tissue with the expectation that the wiring in the rest of the structure follows the same rules. Finally, there is the hope that functional insights gained with any mammalian brains may be applied to ourselves, and that genetically derived pathologies in mice may have clinical analogues in man. However, the system has one great disadvantage: it is currently too expensive deliberately to induce mutations in mice and screen the progeny for a desired phenotype. This means relying on inbred stocks which have been retained because they acted very abnormally—reeling, trembling, twirling, staggering, and so on. Most neurological mouse mutants chiefly affect the cerebellum, whose anatomy is conveniently simple and repetitive, with only five types of cell, and whose circuitry and synaptic interactions are well understood⁵⁴. Unfortunately, the mutants isolated so far are drastic^{54,57}. Two, *weaver* and *staggerer*, cause massive degeneration of granule cells (the most numerous neurones, which receive the major input from the rest of the brain). Two more, *nervous* and *pcd*, lead to loss of the Purkinje cells (the largest neurones, which provide the only output from the cerebellum).

Genetic lesions such as these are useless for understanding the subtleties of neural development or finding out how the normal cerebellum functions to control posture, coordination and balance. They do, however, raise interesting questions about neurogenesis. For example, the mutation *pcd*, in addition to rapid degeneration of cerebellar Purkinje cells, also produces slow degeneration of mitral cells in the olfactory bulb and photoreceptors and induces structural abnormalities in spermatozoa, leaving other cells in the animal unaffected^{57,58}. Are the four affected cell types under similar metabolic stress, which is in some way aggravated by the mutation? It is difficult to see what they have in common. Do the neurones occupy analogous positions in an unrecognised developmental hierarchy, and thus become dependent on the same controlling element? Evidence from other mutations would be needed to consider such an idea seriously.

One important question is whether the primary lesion is actually in the affected cells. Unlike those of nematodes, vertebrate neurones may die from unrequited synapses, either because they lack proper input or because they fail to establish connections with their target cells. Thus, normal granule cells could degenerate because cryptically abnormal Purkinje cells refuse to interact with them or vice versa. This issue has been elegantly settled for the *pcd* mutation. Mullen⁵⁹ made chimaeric mice⁵⁹ whose cerebella contained mixtures of *pcd* and normal cells. By properly selecting parent strains and using enzyme markers, he was able to ascertain the genotypes of individual cells and it was thus possible to show that all the *pcd* cells had atrophied and all the normal cells survived. Therefore, the defect is cell autonomous: that is, if a Purkinje cell dies it is its own (genetic) fault. This is unsurprising. However, the opposite is true for *reeler*, a mutation which generally affects neuronal migration during development and specifically induces abnormal, twisted morphology in Purkinje cells. In chimaeric normal *reeler* cerebella, Purkinje cells of both genotypes were sometimes normal-looking, sometimes abnormal⁶⁰. In this case the morphology of the cells is specified from outside, by the neural environment.

With the mutant *staggerer*, there is some indication that the major observed effect, granule cell degeneration, is due to a defect in the Purkinje cells which fail to form proper dendritic spines, the normal target for granule cell synapses^{61,62}.

So far, in spite of these elegant analyses, the mouse mutants have taught us little about the development of the cerebellum and nothing about its function. However one is of particular interest; *reeler* affects not only the cerebellum but cerebral cortex as well, altering its development radically. The embryonic cortex forms and develops as a hollow shell of cells around the fluid-filled lumen of the anterior neural tube. Neuronal cell divisions occur only on the inside surface of the shell. In normal development, the earliest neurones to form tend to remain near the lumen to form the deepest layer of the cortex, and cells formed at later stages migrate past all the others to lie in more superficial layers. The position of a neurone in the cortex is thus determined largely by the time of its last cell division, with the youngest cells on the outside. In *reeler*, the developing cortical neurones fail to migrate past each other so that the oldest cells remain in superficial layers with younger cells progressively deeper⁶³.

Caviness⁶⁴ has examined the visual area of this 'inside-out' cortex and found that incoming fibres carrying sensory information from the eyes terminate in the correct layer; that is, instead of penetrating the cortex from below, making a few synapses in the deepest layer, then rising to terminate at an intermediate layer, as in the normal mouse, the same fibres immediately ascend to the most superficial cortical layers, form some synapses, then reverse direction to terminate in intermediate layers. This inversion rule also holds true for different classes of output axons coming from the cortex.

When he examined individual neurones in *reeler* cortex, Caviness found that some looked normal, others were apparently inverted, and still others had axons which abruptly reversed direction after leaving the cell soma. The findings above, taken *in toto*, look very discouraging from the mouse's point of view. Nevertheless, physiological recordings by Dräger⁶⁵ show that most of the cells in the *reeler* striate cortex have normal retinotopic organisation and visual response

characteristics, including binocularity and orientation and direction selectivity. The upside-down *reeler* cortex is functionally indistinguishable from the rightside-up normal one.

No one has studied chimaeric cortices containing both normal and *reeler* cells. It would be interesting to see whether normal organisation is enforced on the mutant neurones and, if not, whether proper visual receptive fields persist with competition between normal and inverted cortical organisation.

It is worth noting that Siamese cats are also neurological mutants. The gene (temperature-dependent albinism) which specifies the pale colour of their body fur also reduces the pigmentation of the cells behind the retinas in their eyes⁶⁶. This pigment deficit apparently induces dramatic miswiring of optic nerve fibres carrying visual information to the brain, causing many to reach the wrong destination. This miswiring leads to a cascade of neurological defects in centres involved with vision—in the thalamus, in primary and secondary visual cortex, and perhaps in even higher areas. Although the original mutant defect is probably non-neural, work with the visual system of these cats (reviewed in refs 67–69) may tell us much about the developmental rules which normally lead to proper arrays of neural connections and orderly maps in the mammalian brain.

Conclusion

At its inception 15 years ago, the neurogenetic approach seemed very promising. Since then it has led to many elegant experiments, much tantalising information, and some insight. In general, however, behavioural geneticists have asked one set of questions and answered another. The central questions of neurobiology—the chemical bases of ion gating and synaptic transmission, the mechanisms involved in specifying a neurone's shape and determining its interaction with other cells, the changes in neurones and circuits which underlie learning—are all untouched by the approach. The field is still promising, in the best and the worst sense. If progress in the next decade equals that of the last, the promise will begin to be fulfilled.

We thank Carol Gould, Martha Constantine-Paton and Jeffrey Hall for comments on the manuscript.

Very large array observations of solar active regions

Kenneth R. Lang & Robert F. Willson

Department of Physics, Tufts University, Medford, Massachusetts 02155

The first very large array (VLA) synthesis maps of solar active regions are presented here. The observational capabilities, and the basic techniques of using the VLA to observe the Sun are also described. Comparisons of VLA maps with magnetograms are also made.

OBSERVATIONS of the Sun with three-element interferometers at centimetre wavelengths and angular resolutions of a few arc seconds have shown that solar active regions contain intense (10^5 – 10^6 K), small-scale (less than $15''$), circularly polarised (above 30%) sources which dominate solar emission at these wavelengths and angular resolutions^{1,2}. The radiation from these sources has been interpreted in terms of gyromagnetic processes involving strong magnetic fields and thermal electrons in the dense coronal regions above sunspots^{2–6}. As long as the active regions are not emitting flares, the intensity, angular size, and degree of circular polarisation of the small-scale sources remain remarkably constant for intervals of at least 12h. This stability makes these solar sources ideal candidates for the aperture synthesis technique which has been developed by

radioastronomers to obtain two-dimensional maps of celestial radio sources with arc second angular resolution⁷. When applied to the centimetre wavelength radiation of the Sun, these techniques may be used to test the gyro-resonance absorption theory of this component of solar emission. Moreover, the synthesis technique can be used to obtain high resolution maps of circular polarisation which delineate the magnetic field structure in the solar corona. These structures can then be compared with optical wavelength Zeeman effect observations of the magnetic field in the underlying photosphere and chromosphere. Because of scintillations in the terrestrial atmosphere, these optical wavelength observations are limited to the angular resolutions which are now available at radio wavelengths using the synthesis technique. The first synthesis maps of solar active regions at centimetre wavelengths were obtained using the 12 25-m paraboloids (20 interferometer pairs) of the Westerbork synthesis radio telescope (WSRT)^{8,9}. In this case, a synthesised beam of $6'' \times 22''$ at a wavelength of 6 cm was used to show that solar active regions contain small-scale sources (with peak brightness temperatures as large as 10^6 K and circular polarisations of $\sim 50\%$) surrounded by a lower intensity $\sim 10^5$ K halo.

Fig. 1 The u - v tracks obtained while observing the Sun at 6 cm wavelength with 45 interferometer pairs of the VLA when the Sun is at a declination of 0° . Because the longer baselines were not used in our maps, we have omitted here the 10 tracks from the 10 interferometer pairs connecting to the furthestmost antenna located 10.473 km from the array centre. The dark line at $v = 0$ denotes the tracks obtained while observing the Sun at 6 cm wavelength with the 20 interferometer pairs of the WSRT when the Sun is at a declination of 0° .

Although circularly polarised emission was observed from both sunspots and plage peaks, the more intense emission came from sunspots whose magnetic polarity coincided with the direction of circular polarisation. We describe here synthesis maps of solar active regions obtained using 12 25-m paraboloids (65 interferometer pairs) of the VLA now under construction near Socorro, New Mexico by the National Radio Astronomy Observatory¹⁰. In this case a synthesised beam of $1'' \times 3''$ is obtained at a wavelength of 6 cm.

Construction and operation of the VLA

Twenty-seven antennas are being constructed, tested and placed along the three arms of the WYE configuration of the VLA. The position angles of the north, south-east, and south-west arms are, respectively, 355° , 115° and 236° ; whereas the geodetic coordinates of the array centre are $34^\circ 04' 43.497''$ N (latitude) and $107^\circ 37' 03.819''$ W (longitude). With this configuration and location the most complete spatial frequency coverage is obtained when the Sun is at its larger positive declinations. The

permanent antenna stations are placed along each arm at distances ranging between 0.045 and 21.0 km from the array centre, thereby providing effective angular resolutions ranging between $0.57''$ and $4.44''$ at a signal wavelength of 6 cm for the interferometer pairs along each arm (each combination of two antennae makes one interferometer pair). Similar angular resolutions are available for the interferometer pairs consisting of antennae placed on different arms. The individual antennae have 25 m diameter main reflectors with a feed system¹¹ designed to receive signal wavelengths of 1.3, 2, 6 or 21 cm with respective beamwidths of 1.9, 2.9, 8.6 and $30''$ and respective aperture efficiencies of 46, 54, 65 and 50%. About 1 min is required to rotate the antenna feeds to sample signals at different wavelengths. Two independent systems simultaneously accept two oppositely polarised signals at the chosen wavelength, and these signals are converted into intermediate frequency (IF) signals with bandwidths of 1.5 MHz, 12 MHz or 50 MHz. The two IF signals received at each antenna are sent to a central location where they are multiplied together to give the correlated flux for each oppositely polarised signal for every interferometer pair. Each correlated signal is time averaged to give its amplitude and phase every 10 s.

Fig. 2 The dirty VLA beam pattern at a signal wavelength of 6 cm constructed from observations during the daylight hours on 1 April 1978.

Fig. 3 VLA synthesis maps of solar active region 1046 obtained with one days observation on 30 March 1978. North is up, west is to the right. *a*, The left; and *b*, the right hand circularly polarized signals; $\lambda = 6$ cm.

The present digital system of the VLA is designed to handle up to 12 antennae with two IF signals each, but more sophisticated electronics designed to handle 27 antennae with four IF channels each are being installed. For the observations reported here we used 12 antennae with three antennae positioned along the south-east arm at 0.080, 0.090 and 0.147 km from the array centre and nine antennae placed along the south-west arm at 0.045, 0.484, 0.710, 0.970, 1.589, 3.188, 5.223, 7.659 and 10.473 km from the array centre. Altogether the average correlated flux from 55 interferometer pairs was sampled every 30 s at a signal wavelength of 6 cm for both the left hand circularly polarised (LCP) and right hand circularly polarised (RCP) signals. When observing the Sun at centimetre wavelengths the system noise is completely dominated by the solar brightness temperature of 10^4 – 10^6 K. The theoretical r.m.s. noise fluctuation in the correlated flux density obtained with each antenna pair is 6.4 Jy ($1 \text{ Jy} = 10^{-23} \text{ erg s}^{-1} \text{ cm}^{-2} \text{ Hz}^{-1} = 10^{-26} \text{ W m}^{-2} \text{ Hz}^{-1}$) for a system noise temperature of 10^4 K with our chosen bandwidth of 12 MHz and an integration time of 30 s. We later averaged the data over 5 min intervals to obtain a r.m.s. noise of 2 Jy for each interferometer pair.

Active regions 1046 ($24^\circ \text{S } 7^\circ \text{W}$ at 12h UT on 30 March) and 1056 ($12^\circ \text{N } 65^\circ \text{E}$ at 0h UT on 31 March) were observed on 30 March and 1 April 1978 respectively, at a signal wavelength of 6 cm. For each antenna pair the correlator outputs were calibrated by observing 3C 84 or CTA102 for 5 min every 20 min, whereas the solar active region was observed during the remaining 15 min of each 20-min period. The frequent observations of the calibrator lessened the effects of tropospheric refraction variations, and calibrated the instrumental gain, polarisation and phase fluctuations.

Measurements

For each polarisation of each antenna pair the correlated flux, $S_{mm}(\text{Sun})$, and the corrected phase $(\phi_m^* - \phi_n) - (\phi_n^* - \phi_m)$ when observing the Sun were taken to be the amplitude and phase of the visibility function, $V(u, v)$. Because corrections for the motion of the Sun across the sky, its rotation about its axis, and its horizontal parallax were incorporated in the computer program which determined the pointing of each antenna, the changing values of the visibility function could then be used to measure the brightness distribution of the active region $I(x, y)$, through the fundamental Fourier transform relationship

$$V(u, v) = I(x, y) \exp[+2\pi i(ux + vy)] \quad (1)$$

where the visibility function and the brightness distribution are determined separately for the two circular polarisations, u and v are the projections of the baseline vector in the direction of increasing right ascension and declination, respectively; and x and y are, respectively, coordinates in the direction parallel to increasing right ascension and declination. These quantities, defined in radians, are given by

$$\begin{aligned} u &= B_x \sin(h) + B_y \cos(h) \\ v &= -B_x \sin(\delta) \cos(h) \\ &\quad + B_y \sin(\delta) \sin(h) + B_z \cos(\delta) \end{aligned} \quad (2)$$

where B_x , B_y , and B_z are the topocentric coordinates of the baseline vector in units of the observation wavelength, and h and δ respectively denote the hour angle and declination of the active region.

As the Earth rotates, the hour angle of the active region changes and the projected baseline describes an ellipse in the u - v plane (the Fourier plane of the brightness distribution). The extent of the coverage in the u - v plane depends on the Sun's declination, the orientation and length of the baseline vector of each interferometer pair, and the total number of interferometer pairs. During the observations reported here, for example, the Sun was near the vernal equinox when the Sun's declination passes through zero degrees, and the elliptical u - v tracks degenerate into straight lines. Figure 1 shows the u - v tracks when the Sun is observed at zero degrees declination with the VLA and with interferometers which are orientated in a strictly east-west direction such as the Westerbork synthesis radio telescope (WSRT). For the east-west baselines, v becomes zero for a declination of 0° . Later in the summer or winter, when the Sun's declination can respectively reach $+23^\circ$ and -23° , the extent of the v coverage by the WSRT broadens. For the VLA, the straight lines given in Fig. 1 become shortened or lengthened ellipses, respectively, for the southern and northern declinations.

The correlated flux when observing the Sun for each polarisation with each antenna pair (m, n) was determined from the equation

$$\begin{aligned} S_{mm}(\text{Sun}) &= \frac{R_{mm}(\text{Sun})[T_{mm}(\text{Sun})T_{nn}(\text{Sun})]^{1/2}}{R_{mm}(\text{cal})[T_{mm}(\text{cal})T_{nn}(\text{cal})]^{1/2}} S_{mm}(\text{cal}) \\ &\quad \times \exp[i(\phi_m^* - \phi_n) - i(\phi_n^* - \phi_m)] \end{aligned} \quad (3)$$

where R_{mm} denotes the correlation coefficient (fraction of the total power which is correlated) for one polarisation of the antenna pair (m, n).

$$\begin{aligned} R_{mm}(\text{cal}) &= G_m G_n \frac{S_{mm}(\text{cal})}{[T_{mm}(\text{cal})T_{nn}(\text{cal})]^{1/2}} \\ &\quad \times \exp[i(\phi_m - \phi_n)] \end{aligned} \quad (4)$$

where G_m and ϕ_m respectively denote the magnitude and phase of the complex gain of the detection system of antenna, m , the $S_{mm}(\text{cal})$ is the correlated flux when observing the calibration source with one polarisation of the antenna pair (m, n), and $T_{mm}(\text{cal})$ denotes the system noise temperature when observing the calibrator source with one polarisation of antenna, m .

When observing the solar active region the correlation coefficient, $R_{mm}(\text{Sun})$, for one polarisation of the antenna pair (m, n) is given by

$$\begin{aligned} R_{mm}(\text{Sun}) &= G_m^* G_n^* \frac{S_{mm}(\text{Sun})}{[T_{mm}(\text{Sun})T_{nn}(\text{Sun})]^{1/2}} \\ &\quad \times \exp[i(\phi_m^* - \phi_n^*)] \end{aligned} \quad (5)$$

Because the parametric amplifiers were used for both solar and calibration observations, an extra IF attenuation producing a phase difference $(\phi_m^* - \phi_n)$ had to be inserted when observing the Sun. This phase difference was measured by observing the calibration source with each antenna with the attenuator in and out. The levels of the two IF signals being fed into each multiplier from each antenna were kept at a fixed value using an automatic level control loop in which the sampled signal level controls an attenuator in the final IF amplifier. The automatic level control loop therefore automatically compensates for the variation in gain magnitude caused by the introduction of an extra IF attenuator when observing the Sun. This meant that we could assume that the gain magnitudes are the same when observing the calibrator and the Sun ($G_m = G_m^*$). The system noise temperature, $T_{mm}(\text{cal})$, when observing the calibrator was measured for each antenna using a switched noise source whose temperature of $\sim 3\text{K}$ was accurately calibrated for each antenna by observing the Moon. The system noise temperature, $T_{mm}(\text{Sun})$, when observing the active region was measured for each antenna by determining the difference in the total power detected when observing the active region and a quiet Sun region whose temperature was assumed to be 10^4K . Even at these high temperatures the front-end amplifiers were in their linear, unsaturated regions. Subsequent observations of more intense active regions with antenna temperatures $\geq 10^5\text{K}$ did, however, require the removal of the parametric amplifiers to avoid saturation. In this case, the gain and phase could be calibrated by observing 3C273 with the amplifiers out, but it also had to be observed with the amplifiers replaced in order to measure the system noise temperatures, $T_{mm}(\text{cal})$.

The correlated flux of the calibration source, $S_{mm}(\text{cal})$, was taken to be 49 and 34 Jy, respectively, when observing 3C84 and CTA102. The gain of each circularly polarised channel was calibrated by adjusting the digitised output of the correlators to give the same values of $R_{mm}(\text{cal})$ for every baseline pair and both polarisations. This is essentially because the calibrator sources have negligible circular polarisation and they are effectively point sources for the interferometric baselines used. These instrumental adjustments were also applied to the solar data to obtain the corrected amplitude, $S_{mm}(\text{Sun})$, and the corrected phase $(\phi_m^* - \phi_n) - (\phi_n^* - \phi_m)$ for each polarisation of each antenna pair every 30 s of each 15-min period of solar obser-

Fig. 4 VLA synthesis maps of solar active region 1056 obtained with one days observation on 1 April 1978. North is up, west is to the right. *a*, The left, and *b*, the right hand circularly polarised signals; $\lambda = 6\text{ cm}$.

Fig. 5 A Kitt Peak National Observatory magnetogram of the Sun taken on 29 March 1978. Here Zeeman effect observations of the 8,680 Å line of neutral iron have been used to derive magnetic field structure which is limited by scintillation to 2"–3" angular resolution. As in Figs 3 and 4, north is up and west is to the right, and the dark and light regions respectively refer to regions of negative and positive polarity. The angular scale for the magnetogram is determined by the 32' angular diameter of the Sun. The general features of AR 1046 (lower centre) and AR 1056 (upper left) compare well with the VLA maps shown in Figs 3 and 4.

variations. The 30 s values of amplitude and phase were then added together to obtain 5-min vector averages with a phase calibration better than 5° and an amplitude calibration accurate to <10%. These calibrated data were taken to be the amplitude and phase of the source visibility function, and the source intensity distribution was obtained by Fourier transforming the calibrated data using the Tufts University DEC-10 computer.

VLA synthesis maps and comparisons with magnetograms

The procedure we have implemented involves a direct synthesis of a 'dirty' map which is the convolution of the true brightness distribution with the response function of a point source. This response function, or dirty beam is shown in Fig. 2. It has a FWHM of 1"×3", and the highest sidelobe is 14% of the maximum response.

A deconvolution of the dirty map was then performed using the clean procedure in which the effects of the 14% sidelobes of the synthesised beam were reduced¹². Because both active regions observed were resolved on baselines having fringe spacings <15" we have deleted those data having fringe spacings less than this value; thereby minimising the map noise and reducing computer time. The resultant total intensity contour maps are shown in Figs 3 and 4, where the synthesised beam is represented by a shaded ellipse. Here the contour levels represent 0.9, 0.8, 0.7, 0.6, 0.5, ... 0.2 times the maximum response which had the values of 102, 80, 17 and 5 Jy per synthesised beam area (in units of arc s²), respectively, for AR1046 (LCP), AR1046 (RCP), AR1056 (RCP) and AR1056 (LCP). The r.m.s. sensitivity of the VLA system for 12 h of observation of a 10⁴ K Sun is estimated to be 0.06 Jy.

The most striking aspect of the maps shown in Figs 3 and 4 is that the small-scale sources shown in the LCP and RCP maps are not spatially coincident. They suggest the feet of small dipole magnetic fields with positive magnetic polarity corresponding to the regions with strong right circular polarisation. Region 1046, for example, contains two sources ≈30"×30" in size which are ≥80% LCP with one source of similar angular size and ≥60% RCP located between them. Region 1056 contains one intense component about 30"×30" in angular size with ≥70% circular polarisation. In all cases the small-scale sources are surrounded by less intense halo emission ≥1' in angular extent (large angular sizes >1' are undersampled by the VLA system). Assuming a source size of 30"×30" an intensity of 100 Jy per synthesised beam area (7"×20") and a beam efficiency of 80%, we obtain a

source brightness of $\sim 10^{-11}$ erg s⁻¹ cm⁻² Hz⁻¹ rad⁻². Using the Rayleigh-Jeans law with a wavelength of 6 cm and this value of brightness we obtain a brightness temperature ≈10⁶ K. Thus the small-scale sources and the magnetic structures which give rise to their circular polarisation belong to the higher, hotter, coronal regions of the solar atmosphere. Assuming that the radio emission is at the first few harmonics of the gyrofrequency, magnetic field strengths of the order of a few hundred Gauss are inferred².

The magnetic structures obtained with the VLA can be compared with full disk magnetograms taken daily at the Kitt Peak National Observatory (2"–3" angular resolution) and the Mount Wilson Observatory (12" angular resolution). The magnetograms refer to the cooler regions in the medium to high photosphere, whereas the VLA maps refer to the hotter, higher levels of the solar corona. Figure 5 shows a Kitt Peak magnetogram taken on 29 March 1978 (because of inclement weather both Kitt Peak and Mount Wilson could not obtain data on our days of VLA observation on 30 March and 1 April 1978). The general features for the magnetogram of AR 1046 (in the lower centre of Fig. 5) compare well with the magnetic structure seen in the VLA maps (Fig. 3). The dark feature of negative polarity centred about an axis inclined ~45° West of North corresponds to a similar region in the LCP map, whereas the RCP feature corresponds to the more intense white region of positive polarity. The width of ~1', the extent of ~4', and the separation of components (30"–1') are in agreement for the two maps. Similarly, the magnetogram of AR 1056 (in the upper left hand corner of Fig. 5) agrees well with the VLA map (Fig. 4), for both indicate a predominantly positively polarised region (RCP) of a few arc min in extent. Thus we may conclude that the general magnetic structure inferred from magnetograms for the photosphere agrees with that obtained by VLA observations for the coronal regions.

The VLA is being constructed by the National Radio Astronomy Observatory which is operated by Associated Universities under contract with the NSF. We thank Larry R. D'Addario of the VLA staff for technical assistance, also the Tufts University Computer Staff for computer time for data analysis. Radio interferometric studies of the Sun at Tufts University are supported under contract F19628-79-C-0010 with the Air Force Geophysics Laboratory. We also thank William Livingston of the Kitt Peak National Observatory and Robert Howard of the Mount Wilson Observatory for supplying magnetogram data.

Optimal wavelength region for communication with extraterrestrial intelligence: $\lambda = 1.5$ mm

N. S. Kardashev

Space Research Institute, Moscow, USSR

This article shows that the best capability and reliability of communication at astronomical distances can be achieved at millimetre wavelengths. The cost of communication, and the number of directions in which signals are sent and searched for are assumed to be fixed. A characteristic frequency might be 203.385 GHz, corresponding to the splitting of the ground state of the lightest atom—positronium—and coinciding with the centroid of the relic background spectrum.

SINCE the pioneer work of Cocconi and Morrison¹ it has been assumed that, the optimal search range for transmissions from extraterrestrial civilisations is at short decimetre wavelengths² (near the 21-cm line of atomic hydrogen, the most abundant element). This spectral band lies near the intensity minimum of the cosmic radio background, and the 21-cm line itself has a symbolic value that narrows down the range of frequencies to be searched (it is supposed that transmitting frequency is near the line).

The choice of the decimetre wavelengths remains valid even if there is no information available about the locations of transmitting and receiving parties. But some papers^{3,4} point to the advantage of millimetre wavelengths for other strategies of space communication and take into account the scattering of radio waves in interstellar plasma. The aim here is to provide some confirmation of it.

Let us consider the opposite case: the transmitting side knows a fixed number of directions where signals are to be transmitted. This number might be defined, for example, by the number of stars with conditions suitable for the appearance of life and civilisation. The same assumption can be made by the receiving side: they search for signals from a fixed number of the nearest stars of the required type or from the direction towards the galactic centre. This strategy permits the channelling of signals in narrow (and hence very economical) beams. The assumption about the mutual directivity of transmitting and receiving antennae has been used in analysing most of the previous searches for CETI signals (CETI, communication with extraterrestrial intelligence)

Maximum information capacity and reliability

Let us determine the maximum information flow (or its maximum redundancy if the flow is fixed), with a limited amount of expenditure on the construction and the maintenance of the communication system. What wavelength will be optimal in this case? Assume that P_m and $\Delta\nu$ are the mean power and the bandwidth of the transmitter; A_t and A_r are the effective areas of the transmitting and receiving antennae; T is the noise temperature of the receiving system; R is the distance between the receiver and the transmitter; n_t and n_r are the number of directions in which signals are sent and searched for, respectively.

The mean spectral density of the received signal is

$$S_r = (P_m A_r A_t) / (R^2 \lambda^2 n_t n_r)$$

The spectral information capacity of a communication channel taking into account quantum fluctuations according to Lebedev and Levitin⁵ is:

$$C_r = \ln[1 + z_r(1 - e^{-x})] + [z_r + (e^x - 1)^{-1}] \times \ln\{1 + [z_r + (e^x - 1)^{-1}]^{-1} - x(e^x - 1)^{-1}\} \quad (1)$$

where $z_r = S_r / h\nu$ is the spectral density of the number of signal photons and $x = h\nu / kT$ (here ν is the signal frequency h and k are the Planck and Boltzmann constants). Equation (1) does not contain limitations related to the physical nature of the transmitter and the receiver.

For $z_r \ll 1 - e^{-x}$ and $z_r \ll (e^x - 1)^{-1}$, we have $C_r \approx xz_r$, and the total information capacity is:

$$C = \Delta\nu C_r = (P_m A_r A_t) / (kTR^2 \lambda^2 n_t n_r) = (S_r \Delta\nu) / (kT) \quad (2)$$

in agreement with the well-known Shannon formula. It is important to note that for small signals, equation (2) holds true for any frequency and the quantum effects play no role⁵. In this respect, quantum fluctuations have often been treated inadequately in papers on the CETI problem.

Assume that the expenditures of each side, including maintenance and construction of the system, are $\Sigma \propto A^\alpha / \lambda$, $\alpha = 1 - 2$, that is, the cost increases somewhat faster than the antenna area and is inversely proportional to the wavelength, λ . We believe that this dependence is not anthropocentric because it is associated with expenditures proportional to the mass of the structure and the manufacturing accuracy, taking into account real physical effects.

Fig. 1 Frequency dependence of brightness temperature of the cosmic background radiation (solid line). The data in radio, sub-millimetre and infrared ranges are given for the galactic pole (lower curve) and for the galactic plane (upper curve). The vertical broken line is the centroid of the relic background spectrum.

Let us also assume that the expenditures on the transmitter do not depend on the wavelength (the power of laser generators is the same as, if not higher than, radio generators), and are determined only by the amount of energy consumption.

The value T in the limiting case is determined by the brightness temperature of the cosmic background radiation. Figure 1 shows the frequency dependence of the brightness temperature determined by setting the observed sky intensity to the Planck function at each frequency^{2,6,7}. The dashed line $T = h\nu/k$ ($x = 1$) divides observational data in two parts corresponding to classical and quantum fluctuations.

These data show that:

$$T = \begin{cases} \propto \lambda^{-2.6} & \text{for metre and decimetre waves} \\ 3 \text{ K} & \text{for centimetre and millimetre waves} \\ \propto \lambda^{-1} & \text{for submillimetre and shorter waves} \end{cases} \quad (3)$$

With the assumptions discussed above, we obtain:

$$C \propto \begin{cases} \lambda^{-(1.6 \text{ to } 2.6)} & \text{for metre and decimetre waves} \\ \lambda^{-(0 \text{ to } 1)} & \text{for centimetre and millimetre waves} \\ \lambda^{+(0 \text{ to } 1)} & \text{for submillimetre and shorter waves} \end{cases} \quad (4)$$

The millimetre range therefore seems to be most efficient. Some other arguments in favour of this range should be added.

Let us consider some empirical data about the effects of interstellar plasma on the communication system^{8,9}. The effect of pulse broadening due to the dispersive properties of the plasma is $\Delta t_0 = 8.3 \times 10^{15} \times DM \times \Delta\nu \times \nu^{-3}$ s, where DM is the dispersion measure ($\text{cm}^{-3} \text{ pc}$), $\Delta\nu$ and ν are in Hz. Such a distortion of pulses can be partially eliminated by signal processing, depending on how accurately the dispersion measure is known. The dispersive effect is negligible when

$$\Delta\nu < \Delta\nu_0 = 1/\Delta t_0 = 1.1 \times 10^{-8} \times \nu^{3/2} (DM)^{-1/2} \quad (5)$$

Interstellar scintillation is significant for

$$\nu < \nu_c = 8 \times 10^8 (DM)^{0.75} \text{ Hz} \quad (6)$$

In the case of scintillation, the average time when there is no signal within a bandwidth is:

$$\delta t_s = 2.5 \times 10^{-5} \nu (DM)^{-1} \text{ s}$$

where the bandwidth is smaller than

$$\delta\nu_s = \begin{cases} 10^{-26} \nu^4 (DM)^{-2} \text{ Hz, for } DM < 10 \text{ cm}^{-3} \text{ pc} \\ 10^{-24} \nu^4 (DM)^{-4} \text{ Hz, for } DM > 10 \text{ cm}^{-3} \text{ pc} \end{cases} \quad (7)$$

Scattering also results in a longer duration of signal pulses, given by:

$$\Delta t_s = 0.1/(\delta\nu_s) \quad (8)$$

as well as spectral broadening of quasi-monochromatic signals:

$$\Delta\nu_s = 1/(\delta t_s) \quad (9)$$

Note that the value $\Delta\nu_s$, although small, exceeds the effect of the band broadening associated with the uncertainty or the variability of the Doppler shift of a signal frequency $\Delta\nu_D$. The latter effect also limits the bandwidth to $\Delta\nu \geq \Delta\nu_D = \Delta\nu^{1/2}$ (ref. 10). However, future methods of frequency control and generation should provide the accuracy $\Delta\nu_D \approx 10^{-20} \nu t^{-1/2}$ where t is the measurement time in seconds¹¹. The widest band will then be obtained with $t = 1/\Delta\nu_D$, and will be equal to $\Delta\nu_D \approx 10^{-40} \nu^2$, that is, much less than $\Delta\nu_s$. $\Delta\nu_D$ is also negligibly small for frequencies higher than the critical ν_c (the band $\leq \Delta\nu_D$ can hardly be used because of the small information content and difficulties in generation, detection and receiving).

All the effects mentioned here set limits to possible signal bands and pulse durations. Figure 2 gives regions of possible bands for optimal signals ($\Delta\nu = 1/\Delta t$). Pulses from the transmitter will not fade as long as $\Delta\nu > \delta\nu_s$ or $\Delta\nu < \Delta\nu_0$. There is no signal distortion if $\Delta\nu < 10\delta\nu_s$ and $\Delta\nu < \Delta\nu_0$. In the latter case, the distortion can be partly corrected by signal processing.

Fig. 2 Limits on the bandwidth and pulse duration ($\Delta\nu = 1/\Delta t$) due to the effects of interstellar plasma. Open regions: no limits. Hatched regions: partial restoration of pulse is possible by processing. Doubly hatched regions: attenuated signals cannot be restored.

Note that all of the plasma effects mentioned above decrease rapidly at higher frequencies indicating the advantage of the millimetre range, especially at large distances. The best region corresponds to $\nu > \nu_c$ and since $DM < 10^3 \text{ cm}^{-3} \text{ pc}$ for most of the Galaxy, the millimetre range satisfies this requirement.

Selection of characteristic frequency

We now discuss several frequencies with outstanding symbolic value in the millimetre range. First of all, this band contains most of the energy of the cosmological relic background radiation, the intensity of which dominates all other radiation in this range. The 'centroid' of the relic background spectrum may be considered as a basic characteristic frequency. Integrating the Planck radiation law as follows:

$$\int_0^{\infty} x^3 (e^x - 1)^{-1} dx = \int_{x_r}^{\infty} x^3 (e^x - 1)^{-1} dx$$

one obtains $x_r = 3.50$, which corresponds to a frequency centroid $\nu_r = 197$ to 220 GHz, or a wavelength $\lambda_r = 1.36$ to 1.52 mm for a relic background temperature from 2.7 to 3.0 K (ref. 12).

By a remarkable coincidence a unique radio spectral line falls in this band. It corresponds to the splitting of the ground state of the lightest atom—positronium (P_0). Positronium forms by recombination of an electron and a positron and is about 1,000 times lighter than a hydrogen atom. Laboratory investigation of positronium provided some of the basic evidence for the validity of quantum electrodynamics. The characteristic feature of positronium is the fact that its properties can be calculated from fundamental physical constants. The lifetime of this atom is very short because of the annihilation process, so a high concentration could hardly be expected in natural cosmic conditions.

The ground state of a positronium atom ($n = 1, l = 0$) is split into singlet $^1S_0$ and triplet $^3S_1$ states (where the positron and electron spins are antiparallel and parallel, respectively). According to most accurate theoretical estimates, this splitting corresponds to a frequency of 203,383 267(86) GHz ($\lambda = 1.47$ mm).

The calculated frequency was confirmed with high accuracy in the experiment by Egan *et al.*¹³ to be 203,384 9(12) GHz.

The annihilation times for the given sublevels are: $\tau(^1S_0) = h/(\pi m_e c^2 \alpha^5) = 1.25 \times 10^{-10}$ s for the two γ quanta annihilation, and $\tau(^3S_1) = 9h/[4(\pi^2 - 9)m_e c^2 \alpha^6] = 1.4 \times 10^{-7}$ s for the 3γ -quanta annihilation (m_e is the electron mass, c is the velocity of light, α is the fine structure constant).

These values may be used as adequate symbols to determine, for instance, the pulse duration of a beacon, and that of the basic information flow. Their reciprocal values (8 GHz and 7 MHz respectively) could denote signal bandwidths. We can estimate the maximum recurrence period for such pulses. If only one pulse is emitted in each direction and if such pulses are sent in a sequence to 10^{11} stars, then the signal recurrence period will be 12.5 s and 3.9 h, respectively.

We shall now estimate the information content of a millimetre channel on the basis of current technology. Given $P_m = 1$ MW, $A_t = A_r = 40$ m² (corresponding to a reflector 10 m in diameter), $T = 200$ K, $\lambda = 1.5$ mm, $R = 100$ pc, $n_t = 10^3$, $n_r = 1$, then from equation (2), C is 2 nit per day [where 1 nit = $1/\ln 2 = 1.44$ bit]. If $P_m = 100$ MW and $A_t = 4,000$ m² (100-m reflector) are assumed for the transmitting side, the same result is obtained for $R = 10$ kpc.

Interestingly, monochromatic radiation near the frequency 203 GHz has already been detected from astronomical objects. Phillips *et al.*¹⁴ observed the radio line from the $3_{13}-2_{20}$ transition of the $H_2^{18}O$ molecule, the laboratory frequency of which (203,407.5 GHz) is strikingly close to the positronium-line frequency. Observations were carried out with an antenna of diameter 11 m and a system temperature of 200 K. The line was discovered in emission from molecular clouds near Ori A and

DR 21. The line intensity corresponds roughly to the expected concentration of $H_2^{18}O$ molecules in these clouds. It should be stressed that with such equipment, it is already possible to search for CETI sources in the millimetre range.

In conclusion, we emphasise that the millimetre region is outstanding among all possible ranges of electromagnetic radiation because it is:

(1) A spectral region of minimum brightness temperature (for lower frequencies, the temperature increases due to synchrotron radiation, for higher frequencies, due to radiation of dust and stars).

(2) A spectral region of minimum absorption and scattering. The most economical strategy of space communications is to align the transmitting and receiving antennae and to send the radiation and the information it carries in a narrow beam.

In this case, the features discussed above for the millimetre range in the present cosmological epoch provide for maximum information capacity and reliability of communication for a given expenditure on construction and organisation.

The most prominent millimetre wavelength, within the bandwidth corresponding to the centroid of the relic background is that of the positronium line at 1.47 mm, which nearly coincides with the $H_2^{18}O$ line. Thus a search for CETI signals would yield simultaneous astronomical results. Alternatively, during normal astronomical observations of the $H_2^{18}O$ line there is a possibility of chance discovery of artificial signals. We once again emphasise the necessity of searching for monochromatic and pulsed signals, bearing in mind that beacons might have a fairly large duty cycle. The use of such signals appreciably reduces the average power required for the transmitter. This fact, along with the known frequency and bandwidth, greatly facilitates the search for extraterrestrial intelligence.

I thank J. S. Shklovsky, D. Downes and V. I. Slysh for helpful discussions.

A novel bacteriophage defence mechanism: the anti-restriction protein

Nikolaus Spoerel & Peter Herrlich

Max-Planck-Institut für Molekulare Genetik, Berlin-Dahlem, FRG, and Institut für Genetik der Universität Karlsruhe and Kernforschungszentrum Karlsruhe, Institut für Genetik und für Toxikologie von Spaltstoffen; Postfach 3640, D 7500 Karlsruhe 1, FRG

Thomas A. Bickle

Bacteriophage T3 and T7 protect their DNA from restriction by producing, as the earliest detectable phage functions, anti-restriction proteins. Although the two phage proteins differ in their chromatographic and antigenic properties, they act by the same mechanism: the anti-restriction proteins inhibit E. coli K12 restriction endonuclease by direct interaction.

A PARTICULARLY vulnerable stage of the bacteriophage life cycle is immediately after infection, when the naked DNA is exposed to host cell nucleases, particularly restriction endonucleases. Some bacterial viruses have developed means of combating the host-controlled restriction system by modifying their DNA by, for example, incorporating unusual bases or by glycosylation. The modified DNA is protected from degradation *in vivo* and *in vitro*. The related *Escherichia coli* phages T3 and T7 apparently possess a different mechanism to overcome

Table 1 Effect of increasing Ado-met concentration on the *EcoK* inhibition by SAMase

-SAMase Initial Ado-met (mM)	+SAMase ATP hydrolysed (% of input)	+SAMase ATP hydrolysed (% of input)	ATPase activity (% of control)	Final Ado-met (mM)
0.5	46.5	6.0	13	0.05
1	61.7	22.7	37	0.1
2	57.7	28.2	49	0.2
5	51.9	31.2	60	1.6
10	41.0	21.0	51	5.6

EcoK and SAMase were purified as described elsewhere¹⁰⁻¹⁴ (SAMase A (refs 10, 11) was used in all experiments; SAMase B (refs 10, 11), however, behaved identically). ATPase was assayed using ³H-ATP (refs 12-14) and resolving ATP and ADP by thin-layer chromatography on polyethylenimine after the incubation. Initial Ado-met concentration was calculated assuming '100% purity' of the dry substance used (Boehringer). ¹⁴C-Ado-met levels were determined after chromatography on cellulose thin layer developed with 64% ethanol²¹. Incubations were for 30 min at 30 °C. The incubation volume of 20 µl contained the components and amount of SAMase described in the legend to Fig. 1 except that the concentration of Ado-met was varied. All components were present from the start of incubation.

restriction: they grow on K12 and B strains even though their DNA is a substrate for the restriction enzymes *in vitro*². Mutants of these phages can be found which are efficiently restricted by the *E. coli* systems. Such mutations map in the first gene of T3 (*S*-adenosyl-methionine hydrolase (SAMase), ref. 3 and N.S. *et al.*, unpublished) and also in the first gene of T7 ('0.3' gene⁴, 'M'-gene⁵). Because the T3 mutations occur in a gene coding for an enzyme that hydrolyses *S*-adenosyl methionine (Ado-met), one of the essential cofactors for the *E. coli* K12 and B (*EcoK* and *EcoB*) restriction enzymes, one could explain the anti-restriction activity as a direct consequence of the hydrolysis of Ado-met. No such explanation can be offered for anti-restriction by T7 because this phage does not code for a SAMase.

T3 SAMase and the T3 anti-restriction activity are independent functions of the same protein

Most T3 mutants which are defective in anti-restriction have lost SAMase in the same mutational event (ref. 3 and N.S. *et al.*, unpublished). One *ts* mutant, however, could not overcome restriction at the non-permissive temperature, although it could still induce SAMase activity (ref. 6 and N.S. *et al.*, unpublished; see also Table 4). The inverse phenomenon has also been described: a mutant (3356) retained the anti-restriction phenotype but had lost the SAMase activity⁷. This can be explained by assuming either that the same peptide chain carried two independent activities or that the two activities were exerted by two proteins encoded in the same DNA segment but read in different reading frames⁸. The latter possibility was ruled out, as out of 20 mutants isolated that were defective in both SAMase and anti-restriction activities, seven were found to be *amber* mutants. The isolation of an *amber* mutant has also been reported from another laboratory³. All these *amber* mutants expressed both anti-restriction and SAMase activities in suppressing hosts. As the *amber* mutation is reading-frame specific⁹, both activities must be expressed by the same polypeptide. Thus, the genetic evidence suggests that SAMase activity is not required for anti-restriction.

SAMase inhibits the restriction system *in vitro*

The effect of purified SAMase^{10,11} on restriction was tested using the *EcoK* system. The restriction reaction proceeds in a series of steps¹²⁻¹⁴, including the activation of *EcoK* by Ado-met, the binding to DNA, the triggering of *EcoK* by the unmodified

DNA site to become an endonuclease, and the ATP-dependent endonucleolytic cleavage. The last reaction involves ATP hydrolysis, and ATPase activity was, therefore, taken as a measure of the overall reaction. This activity was indeed strongly inhibited by SAMase (Tables 1, 2). To elucidate which step in the chain of reactions leading to ATPase activity was inhibited, the steps were examined individually. The possibility that SAMase inhibits by blocking access to the *EcoK* recognition sites on the DNA was unlikely, as we demonstrated by gel filtration chromatography that SAMase did not bind to DNA (not shown). The binding of *EcoK* to the DNA depends strictly on the presence of Ado-met¹²⁻¹⁴. Degradation of Ado-met *in vitro* will, of course, block this initial step and all subsequent steps. Various lines of evidence have, however, shown that Ado-met hydrolysis is not the cause or not the only cause of anti-restriction.

Anti-restriction does not depend on Ado-met hydrolysis and SAMase interacts directly with *EcoK*

If the anti-restriction depended on Ado-met hydrolysis, one would expect to be able to relieve the inhibition simply by increasing the initial concentration of Ado-met. In the experiment shown in Table 1, incubations were made with a constant amount of both *EcoK* and SAMase but different concentrations of Ado-met. The amount of ATP hydrolysed by *EcoK* and the amount of Ado-met remaining were measured. Although the Ado-met concentration varied over a 20-fold range, and its concentration at the end of the experiment varied between close to zero and more than five times that necessary to support a maximum *EcoK* reaction, the amount of inhibition by SAMase was constant at about 50% except at the lowest Ado-met concentration. At this low Ado-met concentration the SAMase

Table 2 Interaction between *EcoK* and SAMase

Complete mixture* preincubated for 10 min, then addition of	ATP hydrolysed (% of input)
—	17.0
150 ng SAMase	0.2
75 ng SAMase	4.0
30 ng SAMase	4.2
15 ng SAMase	11.8

* The incubation volume of 20 µl contained the components described in Fig. 1. All components except SAMase were present from the start of incubation. ATP hydrolysis between 10 and 30 min is shown.

hydrolysed essentially all the Ado-met before the *EcoK* reaction could begin. Above the minimum concentration of Ado-met, the inhibition of *EcoK* apparently required no Ado-met hydrolysis. This result indicates that the inhibition is due to a direct interaction between SAMase and *EcoK*.

Further support for this idea came from a series of experiments with the Ado-met analogue, *S*-adenosyl homocysteine (SAH), which is a potent inhibitor of both *EcoK* and SAMase^{10,11,15}. SAH competes with Ado-met in the first step of the *EcoK* reaction. If SAH was present from the beginning of the incubation, *EcoK* ATPase activity was inhibited (Fig. 1a). On addition of SAMase, *EcoK* was inhibited further, even with high SAH concentrations (Fig. 1a), despite the fact that Ado-met hydrolysis was prevented (Fig. 1c). As expected from the reaction mechanism, SAH was unable to inhibit *EcoK* if it was added late in the reaction at times when free Ado-met was no longer required (Fig. 1b). However, when SAMase was added with SAH late in the reaction, inhibition was observed. The degree of inhibition was constant over all SAH concentrations and thus independent of the amount of Ado-met hydrolysis (Fig. 1b). In fact, it depended solely on the amount of SAMase (Table

2). Changing the proportion of SAMase to *EcoK* caused inhibition of ATPase of between 0 and 100%. The time course (not shown) and reversibility (see below) of the reaction suggest a non-catalytic interaction. Although the proportion of active enzyme in both preparations *EcoK* and SAMase is somewhat uncertain, an approximately stoichiometric interaction is compatible with our data.

The experiment in Fig. 1b showed that SAMase could inhibit *EcoK* after proper binding to DNA. The inhibition of activated *EcoK*-DNA complexes was also measured directly. Such complexes, purified by passage through Biogel, hydrolyse ATP. The hydrolysis was still inhibited by the addition of SAMase (not shown) although Ado-met was no longer required for *EcoK* ATPase and was only present in concentrations (10^{-10} M) far below the K_m of SAMase^{10,11}. These data confirm the conclusions from the genetic results described initially that Ado-met hydrolysis is not required for anti-restriction and that the SAMase protein purified for its affinity to SAH^{10,11} causes anti-restriction by interaction with *EcoK* after the Ado-met-mediated step.

Fig. 1 The influence of SAH on anti-restriction *in vitro*. The reaction mixtures contained in a total volume of 20 μ l (refs 12-14): 2 μ mol HEPES, pH 8.0, 1.4 nmol EDTA, 60 nmol 2-mercaptoethanol, 0.12 μ mol $MgCl_2$, 0.2 μ g unmodified λ (0) DNA, 1.1 nmol purified Ado-met¹²⁻¹⁴ (^{14}C Ado-met at 22 Ci mol⁻¹), 2 nmol ATP (^3H -ATP at 540 Ci mol⁻¹), 100 ng *EcoK* plus 60 ng SAMase where indicated. SAH was added as plotted in the abscissa. ATPase activity was determined as described elsewhere¹²⁻¹⁴. a, Action of SAMase on the overall reaction. All components were present at 0 min. Incubation was for 30 min. x, Minus SAMase; o, plus SAMase. b, Action of SAMase on the activated DNA-Ado-met-*EcoK* complex. ATP, SAH and SAMase were added after 10 min of preincubation of the other components. Further incubation was for 20 min. x, Minus SAMase; o, plus SAMase. c, Ado-met hydrolysis in the incubation mixtures of a. Ado-met remaining at the end of incubation was plotted (in %).

Table 3 Inhibition of SAMase anti-restriction by antibodies

	ATP hydrolysed (% of input)	ATPase activity (%)
Expt 1		
-SAMase (control)	32.9	100
+SAMase at 10 min	8.5	26
+SAMase plus anti-SAMase at 10 min	22.4	68
Expt 2		
-SAMase (control)	40.3	100
+SAMase	12.1	30
+SAMase, + additional Ado-met at 10 min	15.9	39
+SAMase, + anti-SAMase at 5 min	10.4	26
+SAMase, + anti-SAMase at 5 min, + additional Ado-met at 10 min	29.3	73

The assays and incubation mixtures were as in Table 1 and Fig. 1. The anti-SAMase antibodies were prepared as described^{10,11} (anti-SAMase A and anti-SAMase B were equally effective). The amount of antibody added did not interfere by itself with *EcoK* ATPase. SAMase was present from the start of incubation where indicated.

Experiments with antibodies against SAMase directly support the idea of an interaction between the two enzymes, *EcoK* and SAMase. Not only could anti-SAMase added with SAMase to the preincubated *EcoK*-DNA complex totally prevent inhibition (Table 2, expt 1), it could also reactivate *EcoK* after SAMase had been permitted to act (Table 3, expt 2). This clearly shows that the interaction between SAMase and *EcoK* is readily reversible because, if it were not, the antibodies would have precipitated *EcoK* with the SAMase. The reversibility of the interaction was confirmed in gel filtration experiments (not shown): the association of the two enzymes did not survive passage through a Biogel column.

The antibody experiment also provided support for the model of the *EcoK* reaction mechanism¹²⁻¹⁴, which predicts that cleavage of Ado-met after the initial step does not influence the subsequent course of the restriction reaction. The antibodies are somewhat unusual because although they precipitate SAMase, they do not inhibit its enzymatic activity^{10,11}. In the experiments shown in Table 3, both ATP hydrolysis and Ado-met cleavage (not shown) were monitored. As expected, the presence of the antibodies did not prevent the hydrolysis of essentially all the Ado-met, but had a dramatic effect on the inhibition of the activated *EcoK*. Restriction could proceed in the absence of Ado-met.

Properties of purified mutant SAMase enzymes

To investigate whether the anti-restriction reaction observed *in vitro* reflected the physiological anti-restriction mechanism, we isolated mutant proteins of phage with known *in vivo* phenotypes and tested their behaviour *in vitro*. The mutant proteins were purified as cross-reacting material from lysates of cells infected with different SAMase mutant strains, using anti-SAMase immobilised on agarose. The properties of all except one of the isolated mutant proteins were what would be expected from their phenotype *in vivo* (Table 4): the point mutant SAMase 17 eliminated both anti-restriction and SAMase *in vivo*; the isolated protein showed neither activity *in vitro*. T3 3356 could overcome restriction *in vivo* without inducing Ado-met cleaving activity—cross-reacting material from 3356 was SAMase negative but inhibited *EcoK* ATPase. So far, *in vivo* and *in vitro* phenotype correlate well, indicating the physiological role of the anti-restriction reaction *in vitro*. Cross-reacting material was also prepared from a mutant thermolabile for anti-restriction and thermoresistant for SAMase activity (SAMase 15 21). The isolated protein displayed no temperature sensitivity for anti-restriction *in vitro* (Table 4), suggesting that this thermolability occurred only in specific intracellular conditions.

Table 4 Inhibition of *EcoK* ATPase by mutant SAMase proteins

Protein from:	Incubation temperature (°C)	Ado-met hydrolysis	ATP hydrolysed (% of input)	ATPase activity (%)
—	30	—	55.4	100
Non-infected cells	30	—	46.4	84
T3 SAMase 17	30	—	38.8	70
T3 SAMase ts 21	30	+++	16.0	29
T3 3356	30	—	20.1	36
T7	30	—	42.6	77

T3 SAMase ts 21	42	+++	24.0	33

The assays were carried out as in Table 1 and Fig. 1. Mutant protein was obtained as follows: non-infected *E. coli* B_S-1 or B_S-1 at 8 min after infection^{10,11} were disrupted. An S30 was prepared and adsorbed to anti-SAMase IgG attached to Sepharose 4B. Protein was eluted by 6 M LiCl and precipitated by (NH₄)₂SO₄. 10 µg of dialysed protein was added to incubation mixtures. Non-infected cells and T7-infected cells contained no specific cross-reacting band (as judged from SDS gel). IgG was purified from anti-SAMase A antiserum^{10,11} by DEAE-cellulose chromatography²² followed by chromatography on protein A Sepharose²³ and coupled to Sepharose 4B (ref. 22). All infections resulted in <1% surviving cells. T3 SAMase 17 and 21 were isolated for inability to overcome B restriction (ref. 6 and N.S. *et al.*, unpublished). T3 SAMase 17 is a point mutation which induces no SAMase activity. T3 SAMase ts 21 induces SAMase activity *in vivo* at any temperature. T3 3356 (ref. 7) is SAMase negative, anti-restriction positive.

The T7 anti-restriction protein is unrelated to SAMase but exerts a similar action mechanism

We attempted to purify the anti-restriction protein coded by phage T7 using the anti-T3 SAMase affinity column. However, the T7 protein did not bind to the column (Table 4), indicating that it is immunologically not closely related to the T3 SAMase. Extracts from T7-infected cells also contained no cross-reacting material as judged by immunodiffusion^{10,11} and gel overlay techniques (not shown). The T7 anti-restriction protein was, therefore, partially purified using the *EcoK* inhibition assay. Although SAMase did not adsorb to DEAE cellulose^{10,11}, *EcoK*-inhibiting activity from T7-infected cells was only eluted by high salt concentrations (Fig. 2). Such activity was absent when cell extracts from non-infected cells (not shown) or from cells infected with a T7 *M* deletion mutant (Fig. 2) were used. The T7 anti-restriction protein had no affinity to SAH, which is our standard affinity ligand for the purification of SAMase. Although so different, the inactivation of *EcoK* seemed to occur by a similar mechanism, that is, direct interaction. Like SAMase, the T7 anti-restriction protein could inhibit *EcoK* ATPase at a step after the binding to DNA (Fig. 2).

Is anti-restriction the only function of SAMase and of the T7 anti-restriction protein?

Bacteriophage T3 and T7 protect their DNA from restriction by directing the synthesis of anti-restriction proteins. These proteins are the first detectable phage gene products to be made after infection. A consideration of the numerology of these proteins makes it unlikely that either Ado-met hydrolysis (in T3) or anti-restriction (in T3 and T7) are the exclusive roles of these proteins. Each *E. coli* K12 cell is estimated to contain about 10 molecules of *EcoK* (ref. 15); the intracellular Ado-met concentration is of the order of 1 µM and thus each cell contains about 500 molecules of this cofactor¹⁶. Also, the T3 SAMase is among the most abundant of the phage-coded proteins (compare the densities of protein bands in Fig. 1, tracks 5 and 12, in ref. 10) with each cell containing about 10,000 molecules^{10,11}. That is,

Fig. 2 Purification and action of the T7 anti-restriction protein. *E. coli* B_S-1 were infected with either T7 wild type or T7 D9 at a multiplicity of infection of 10, and collected 8 min later. The cells were disrupted as described elsewhere^{10,11} and 3 ml of an S100 adsorbed to DEAE Sephadex (10 ml bed volume) which had been equilibrated with 10 mM Tris-HCl, pH 7.5, 22 mM NH₄Cl and 1 mM dithiothreitol. Adsorbed protein was eluted using a linear gradient of 22 mM to 1 M NH₄Cl in the same buffer. Aliquots of 0.1 µl of each fraction were added to 20 µl containing activated *EcoK*-Ado-met-DNA complexes plus the components described in Fig. 1. There was no ATPase-inhibiting activity in the non-adsorbed protein. Protein eluted between 0.1 and 0.4 M salt degraded essentially all ATP, ADP and AMP. This activity was similar in both types of extracts; T7 wild type and T7 D9. The graph shows activity which was eluted beyond 0.45 M NH₄Cl. x, T7 wild type; o, D9. T7 D9 carries a deletion of the T7 *M* gene ('0.3 gene', see also ref. 5). Surviving cell count in both infections was 0.05%.

1,000 SAMase molecules per *EcoK* and 20 SAMase molecules per molecule of Ado-met. Similarly, the T7 anti-restriction protein is made in large amounts. We thus have the unusual situation that the enzyme is made in vast excess over its putative substrates. The overproduction suggests an additional role for both anti-restriction proteins. This has been independently suggested by experiments with pleiotropic T7 anti-restriction mutants which at the same time could not induce typical virus-dependent membrane alterations nor exclude super-infecting virus^{5,17}.

The *in vivo* time course of anti-restriction introduces another unanswered question. How does T3 and T7 DNA escape restriction before SAMase and M protein synthesis? It is well known from work with phage λ that restriction is a fast process¹⁸. T3 and T7 infection may involve a delay of restriction possibly related to the membrane alteration which occurs before protein synthesis¹⁷.

The mechanism of anti-restriction described here may serve as a model for future research into other anti-restriction systems. There are indications in the literature to suggest that anti-restriction is a general property of many bacteriophages (refs 19, 20 and S. Iida, W. Arber and T.A.B., unpublished).

During a recent EMBO workshop in Paris, we learned that K. K. Mark and F. W. Studier of Brookhaven National Laboratory had carried out similar experiments and obtained results in agreement with ours. We thank them for communicating their data. According to Mark and Studier (unpublished), purified T7 0.3 protein is very acidic. It inhibits the *EcoB* restriction nuclease but does not affect several type II restriction enzymes; the mechanism seemed to be stoichiometric rather than catalytic.

We thank Drs Heinz Schuster and Helmut Ponta for discussion. This work was supported by grants from the Deutsche Forschungsgemeinschaft and the Swiss National Foundation for Scientific Research. This work forms part of the thesis of N.S.

Detection of strong H₂O emission from galaxy NGC4945

AFTER the first detection of the 6₁₆-5₂₃ transition of water vapour in an external galaxy by Churchwell *et al.*¹ in M33, other detections were reported by Lépine and dos Santos² in NGC253, and by Huchtmeier *et al.*³ in M33 and IC342. We report here the detection of H₂O maser emission from NGC4945, a bright edge-on spiral galaxy in the Centaurus group. This is intrinsically the most powerful H₂O maser yet detected in any astronomical source. The search for H₂O emission in NGC4945 was motivated by the previous detection of OH and H₂CO absorption by Whiteoak and Gardner⁴ and Gardner and Whiteoak⁵, and also by the similarity of this galaxy to NGC253. The observations were made on 20-22 September 1978, with the 13.7-m Itapetinga radiotelescope equipped with a ruby maser amplifier with an apparent SSB system temperature of about 150 K. The signal was analysed by a 46-channel, 100-kHz (1.35 km s⁻¹) resolution filter bank, and observations were made with the filter bank centred at different frequencies to obtain greater velocity coverage. The 4' beam was pointed towards the nucleus of the galaxy. The overall dimensions of the galaxy are 17' × 3'. The telescope was beam switched at a rate of 100 Hz. The beams were separated by 9.4 arc min and the reference beam was displaced in azimuth, which did not correspond to a fixed direction with respect to the equatorial plane of NGC4945. Antenna temperatures were corrected for atmospheric attenuation and random attenuation using the standard procedure at Itapetinga⁶ and then converted to flux units, the error in the flux scale being ~10%.

The H₂O spectrum of NGC4945 in the velocity range of 630-750 km s⁻¹ (LSR) is presented in Fig. 1. Emission features >5 Jy appear at 668, 674, 698 and 714 km s⁻¹. No other features >3 Jy appeared in the observed velocity range 560-770 km s⁻¹. The feature at 674 km s⁻¹ is probably not resolved and could still be stronger than 12 Jy; its intensity as observed with 100-kHz channels was confirmed by making shifts of the local oscillator. It corresponds to an intrinsic power ~10 times greater than that of the strongest H₂O source in our galaxy, W49, during its maximum period of emission, if NGC4945 is at a

distance of 4 Mpc (ref. 7). The existence of such strong H₂O sources in the Universe raises the possibility of detection of H₂O from galaxies at even larger distances; for instance, an emission similar to that of NGC4945 could have been detected with our receiving equipment if the source were at a distance twice as large.

The velocity range of the H₂O emission coincides precisely with that of the 1,612-MHz OH emission⁴, suggesting that the same region of the galaxy could be responsible for both masers.

Fig. 1 The H₂O (6₁₆-5₂₃) spectrum of NGC4945. To convert to heliocentric velocities 4.7 km s⁻¹ should be added to LSR velocities.

Gardner and Whiteoak⁴ discuss the possibility of an association of the OH maser with the nuclear region, and point out that the far-infrared radiation from the nucleus is probably the OH pump source. It should be noted, however, that the HI profiles obtained by Whiteoak and Gardner⁸ at different positions along the optical major axis suggest that the velocity range of the H₂O emission may correspond to regions situated to the north-east of the nucleus. A more precise determination of the position of the H₂O masers with respect to the radionucleus (~30" diameter⁹) is planned for a future run of the maser receiver.

We thank A. M. Gomez Balboa for observational help. The maser receiver used in the observations was built at Haystack Observatory as a result of a bilateral scientific agreement established between the US and Brazilian governments. This research was supported by FINEP.

²³⁵U enrichment by pulse gas diffusion

LIGHT-WATER nuclear reactors use uranium fuel enriched in isotope ²³⁵U. One of the enrichment processes is gaseous diffusion. This process is used in large-scale plants in the US and uses the fact that, in the Knudsen diffusion condition, ²³⁵UF₆ diffuses through the porous membrane at slightly higher rate than ²³⁸UF₆. A transient Knudsen diffusion process is proposed here which gives a higher enrichment factor for the lighter species compared with a steady state diffusion process. Because of the higher enrichment, the number of stages required for enriching ²³⁵U to a concentration level suitable for nuclear power reactor fuel is considerably reduced.

The Knudsen diffusion coefficient is reciprocally proportional to the square root of the molecular weight. The difference in molecular weight between ²³⁸UF₆ and ²³⁵UF₆ is 0.86%, and the concentration ratio of ²³⁵UF₆ to ²³⁸UF₆ increases by diffusing through a membrane by 0.429%. Because of the low enrichment factor, many stages are required to concentrate ~0.7% ²³⁵U, in nature, to about 3% as a reactor fuel. A higher enrichment is achieved, however, if the process is operated in the transient condition described here.

Suppose a gas is imposed as a pulse (concentration C_0 for time t_0) on one side of the membrane with small pores in which diffusion is of Knudsen type (effective diffusion coefficient αD_* , membrane thickness L , and porosity a). If the gas concentration on the other side of the membrane is zero, the system is

$$a \frac{\partial C}{\partial t} = \alpha D_* \frac{\partial^2 C}{\partial x^2} \quad (1)$$

at $t = 0$, $C = 0$; at $x = 0$, $C = C_0$, $0 < t < t_0$, $C = 0$, $t > t_0$; at $x = L$, $C = 0$.

The diffusion flux Q at the outlet side ($x = L$) of the membrane is

$$Q = -\alpha D_* \left(\frac{\partial C}{\partial x} \right)_L \quad (2)$$

Substituting the solution to equation (1) into equation (2), we obtain

$$Q = \frac{C_0 D_*}{L} A \quad (3)$$

$$A = \alpha \left\{ 1 + 2 \sum_{n=1}^{\infty} (-1)^n \exp(-(n\pi)^2 \alpha T) \right\} \quad \text{for } t \leq t_0 \quad (4)$$

and

$$A = 2\alpha \sum_{n=1}^{\infty} (-1)^n \{ \exp(-(n\pi)^2 \alpha T) - \exp(-(n\pi)^2 \alpha (T - T_0)) \} \quad \text{for } t \geq t_0 \quad (5)$$

$$\text{where } T = \frac{D_* t}{aL^2} \quad \text{and} \quad T_0 = \frac{D_* t_0}{aL^2}$$

The amount of gas diffused through the membrane for the time from 0 to t_* is

$$S = \int_0^{t_*} Q dt = aLC_0 B \quad (6)$$

$$B = \alpha T_* + 2 \sum_{n=1}^{\infty} \frac{(-1)^n}{(n\pi)^2} \{ 1 - \exp(-(n\pi)^2 \alpha T_*) \} \quad \text{for } t_* \leq t_0 \quad (7)$$

$$B = \alpha T_0 - 2 \sum_{n=1}^{\infty} \frac{(-1)^n}{(n\pi)^2} \{ \exp(-(n\pi)^2 \alpha T_0) - \exp(-(n\pi)^2 \alpha (T_* - T_0)) \} \quad \text{for } t_* \geq t_0 \quad (8)$$

$$\text{where } T_* = \frac{D_* t_*}{aL^2}$$

The total amount of gas diffused through the membrane is, by putting $T_* = \infty$ in equation (8)

$$S_{\infty} = aLC_0 \alpha T_0 \quad (9)$$

The flux of the gas diffused out of the inlet side ($x = 0$) at time t (where $t > t_0$) is

$$Q' = \alpha D_* \left(\frac{\partial C}{\partial x} \right)_0 = \frac{C_0 D_*}{L} 2\alpha \sum_{n=1}^{\infty} \{ \exp(-(n\pi)^2 \alpha (T - T_0)) - \exp(-(n\pi)^2 \alpha T) \} \quad (10)$$

Let us define the effective diffusion coefficient of the heavier species ²³⁸UF₆ by D_* ; $\alpha = 1$. The effective diffusion coefficient of ²³⁵UF₆ is, therefore, αD_* with $\alpha = 1.00429$. In writing concentrations the species ²³⁵UF₆ and ²³⁸UF₆ will be distinguished, respectively, by the superscripts 5* and 8*. The concentrations in the feed are denoted by the subscript 0, and those after the diffusion through a membrane by 1.

The amount of ²³⁵UF₆ diffused through the membrane for the time from 0 to t_* is $S(\alpha = 1.00429)$ and that of ²³⁸UF₆ is $S(\alpha = 1.0)$. The concentration ratio of ²³⁵UF₆ to ²³⁸UF₆ in the collected gas is then

$$\left(\frac{C^{5*}}{C^{8*}} \right)_1 = \frac{S(\alpha = 1.00429)}{S(\alpha = 1.0)} = \frac{C_0^{5*}}{C_0^{8*}} (1 + R) \quad (11)$$

where R is the enrichment factor for the lighter species ²³⁵UF₆.

$$R = \frac{B(\alpha = 1.00429)}{B(\alpha = 1.0)} - 1 \quad (12)$$

Figure 1 shows the enrichment factor R for ²³⁵UF₆ in the gas collected for the time from $T = 0$ to T_* . When T_* is small, the amount of gas decreases, but the enrichment factor becomes very high. If the diffused-through gas is collected for the time from 0 to ∞ , the enrichment factor is $R = 0.429\%$, which is identical with that of the steady diffusion process.

Equation (10) shows that the gas diffused out of the inlet side, at $t > t_0$, also has more of the lighter component than of the heavier, but the enrichment factor for the lighter species is less than that of the steady process.

Fig. 1 Enrichment of $^{235}\text{UF}_6$ in gas collected at outlet side of membrane from time $T = 0$ to T_0 .

After the pulse input is turned off, it takes some time for the gas held in the membrane to diffuse out. In case of $T_0 = 0.04$ – 0.06 , equations (5) and (10), respectively, show that no more gas diffuses out of the outlet side and inlet side of the porous membrane after $T = 0.7$. The process is then repeated by imposing the gas mixture on the inlet side of the membrane.

The enriched gas collected from the first enrichment stage is pumped to the second stage for further concentration. If N stages are used having the same operating conditions of pulse period and gas collection time, the concentration ratio of $^{235}\text{UF}_6$ to $^{238}\text{UF}_6$ in the gas obtained from the final stage is

$$\left(\frac{C^{5*}}{C^{8*}}\right)_N = \frac{C_0^{5*}}{C_0^{8*}} (1+R)^N \quad (13)$$

When 0.7% $^{235}\text{UF}_6$ is concentrated to 3%, equation (13) becomes

$$\frac{0.03}{0.97} = \frac{0.007}{0.993} (1+R)^N$$

If $R = 3\%$, the theoretical number of stages is $N = 50$. In steady diffusion process, however, the enrichment factor is only $R = 0.429\%$ and the number of stages becomes as many as $N = 345$.

Vycor type of porous glass may be used as a membrane for the enrichment process. In fact, the measurements made in our laboratory for a gaseous mixture of nitrogen and argon with a 0.12 cm-thick Vycor glass (mean pore radius 45 Å, and porosity 30%) indicated that the lighter species, nitrogen, was considerably enriched in the gas diffused through the Vycor glass at small times, as predicted from the theory.

The effective diffusion coefficient D_e is

$$D_e = \frac{a}{\tau} D_K \quad (14)$$

where D_K is the Knudsen diffusion coefficient, and τ is the tortuosity factor. The Knudsen diffusion coefficient is

$$D_K = \frac{2\bar{v}r}{3} \quad (15)$$

where r is the pore radius. The mean molecular velocity is $\bar{v} = (8R\theta/\pi M)^{1/2}$ where R , θ and M represent, respectively, the gas constant, temperature and molecular weight. According to Satterfield and Sherwood¹, the tortuosity factor for Vycor glass is $\tau = 5.9$.

With the tortuosity value, the effective diffusion coefficient of $^{238}\text{UF}_6$ in the Vycor glass having $a = 0.3$ and $r = 45$ Å is estimated as $D_e = 0.0002 \text{ cm}^2 \text{ s}^{-1}$ at 25 °C.

Suppose the chambers on either side of the Vycor glass plate are, first, evacuated, and then the gaseous mixture of $^{235}\text{UF}_6$ and

$^{238}\text{UF}_6$ is introduced into one chamber as a pulse for 3 s. If the Vycor glass plate is 0.2 cm thick, $T_0 = 0.05$. If the gas diffused through the plate is collected for 0–3 s (or $T_e = 0.05$), $^{235}\text{UF}_6$ is enriched in the gas by 2.7%.

Equations (6) and (7) indicate that the amount of $^{238}\text{UF}_6$ diffused through the plate for the time from 0 to $T_e = 0.05$ is $S = aLC_0B$ with $B = 0.00028$. If the transient diffusion process is repeated in a cycle of $T_{\text{cycle}} = 0.7$, this quantity S is the amount of $^{238}\text{UF}_6$ obtained for the time $T = 0$ – 0.7 .

On the other hand, in steady diffusion condition the amount of $^{238}\text{UF}_6$ to be obtained for the same time $T = 0$ – 0.7 is $S_s = 0.7aLC_0$.

The amount of gas diffused through the porous membrane in the transient condition becomes much smaller than that in the steady condition. This disadvantage is unavoidable in the transient diffusion process, but it will be attractive in that the lighter species is considerably enriched in the gas obtained in a small time.

Re-evaluation of possible historical relationship between magnetic intensity and climate

HYPOTHESES concerning changes in the internal component of the geomagnetic field and consequent effects on climate^{1–10} are usually based on palaeomagnetic and palaeoclimatic data. Results are often ambiguous due to poor temporal and spatial resolution and difficulties in interpreting the proxy data^{10–12}. Use of historic data partially avoids these problems. Thus, Wollin *et al.*¹³ tentatively conclude “that the trends in intensity from most of the magnetic observatories in the world with records over at least 30 yr correlate negatively with the 10-yr means of air temperature”. Because temperature and magnetic field intensity both have regional characteristics, this conclusion implies that the relationship is a local phenomenon although it will be valid globally. This further suggests that the relationship is causal. Wollin *et al.* presented graphs of mean annual magnetic intensities from 16 magnetic observatories along with 10-yr mean temperatures from nearby meteorological stations; one example is given using a 10-yr running average of winter temperatures and five examples use annual temperatures. Although the graphical data are suggestive of the proposed relationship, the study suffers in three respects. First, data from only 22 of the 43 magnetic observatories listed are presented. Second, the use of 10-yr temperature means yields only three or four data points which may not properly represent the trend of the temperature data. Third, the degree of correlation is not quantitatively evaluated. Here we present statistical evidence that there is no globally valid inverse relationship between geomagnetic intensity and climate for the period covered by observatory records.

We initially selected 98 magnetic observatories¹⁴ which were in reasonable proximity to meteorological stations¹⁵. A record is considered usable if it contains at least 18 yr of data, a maximum number of missing data points equal to 10% of the record length, and no more than one consecutive missing datum. Missing points are linearly interpolated using data from the preceding and succeeding years. Applying these criteria leaves

Fig. 1 Geographic pattern of change in the magnetic field strength, r_{TF} , for 88 records (one record used twice with different meteorological stations). +, Indicates field strength linearly increasing with time (0.001 confidence level); -, Indicates decrease with time; 0, indicates no significant trend. These records represent different intervals of time over the past 70 yr.

89 records from 85 stations. Only the relationship between mean annual geomagnetic intensity and temperature is investigated, even though Wollin *et al.* believe that some stations have intensities correlating with winter temperature trends. No stations are excluded from analysis *a priori*, although Wollin *et al.* suggest that the lack of correlation observed for some stations may be due to climatic influences of strong ocean currents.

We investigated the possibility of a linear relationship between temperature and intensity. Cross plots of these two variables show no evidence of a monotonic nonlinear relationship. Correlation coefficients between magnetic intensity and time (r_{IT}), temperature and time (r_{IT}), and temperature and intensity (r_{TI}) were computed for the various records. The geographical distribution of magnetic observatories and the trends for the r_{IT} values are shown in Fig. 1. The histograms of Fig. 2 summarise results from all records used for the three correlation coefficients. Since the magnetic intensity variation has been linear (low frequency), we did not consider the possibility of a frequency dependent relationship. Zero lag was used in computing r_{TF} which seems reasonable considering the linear variation of intensity and our primary concern in trends rather than high frequency changes. The z transformation of Fisher¹⁶ is used to transform the correlation coefficient r by the formula $z = 0.5 \log_e(1 + r/1 - r)$. As r goes from -1 to 1 , z goes from $-\infty$ to $+\infty$. This transformation is advantageous because for any population of correlation coefficients, the distribution of z will be nearly normal, and the standard error of z will have the simple form $S_z = 1/(n-3)^{1/2}$ where n is the number of points for which r is calculated. Figure 3 shows a histogram of the transformed z/S_z values corresponding to r_{TF} . If the r_{TF} values were randomly drawn from a single distribution with a population mean of zero, the z/S_z values would have a standard normal distribution. It is obvious from the outliers that the values do not represent a single population. To quantify the results, we applied several statistical tests¹⁶⁻¹⁸ to the z_{TF} data. Assuming that the

z values are drawn from a single population, a weighted mean and standard error of the mean can be estimated as $\bar{z} = \sum z/S_z^2 / \sum 1/S_z^2$,

$$S_z = \frac{1}{(\sum (n-3))^{1/2}}$$

with the summation taken over the n records. The calculated values are $\bar{z} = -0.89$ and $S_z = 0.019$. A χ^2 test can then be used to see if the z values differ significantly among themselves, the test statistic being $\chi^2_{N-1} = \sum (n-3)(z - \bar{z})^2$. The calculated value is $\chi^2_{88} = 20,140$ which is highly significant, indicating that the z values and hence the correlation coefficients of r_{TF} do not represent a single population. Thus, the $\bar{z}$ and S_z values derived above cannot be considered valid population estimates. A χ^2 test can then be used to test for an overall association between intensity and temperature by use of the statistic $\chi^2_N = \sum (n-3)z^2$. For this test, $\chi^2_{89} = 22,373$ which is also highly significant. The χ^2 statistics are highly influenced by the relatively few outliers observed in Fig. 3. Because of the linear nature of the geomagnetic intensity temporal variation seen in the r_{IT} histogram of Fig. 2, whenever a temperature record is long and linear, the result will generally be a high z_{TF} value. So the χ^2 tests are not sensitive to subtle overall relationships. A sign test should be more indicative in testing the hypothesis as it gives information on the sign of the z values independent of their magnitude. The proposed inverse relation would suggest a preponderance of negatively signed r_{TF} or z_{TF} values. Out of the 89 records, 52 have negative r_{TF} values. Using the normal approximation to the binomial test with continuity correction,

$$P(r^- > 52) \approx P(Z > \frac{51.5 - 44.5}{89/4}) \approx 7\%$$

where Z here means the standard normal distribution. This is borderline statistical significance.

Fig. 2 Correlation coefficients of 89 records from 85 pairs of magnetic and weather observatories. Separate histograms are for the correlation between total magnetic intensity and time (r_{TM}), temperature and time (r_{TI}), and temperature and total intensity (r_{TF}).

Since geomagnetic intensity and climate are both regional parameters showing temporal and spatial coherence regardless of the hypothesis being considered here, data used to analyse the present hypothesis should be well distributed geographically. Otherwise, a spurious regional correlation between intensity and climate might unduly bias the overall results. Of the 89 records, 37 are from European stations although Europe covers only about 2% of the Earth's surface. The European z values were combined into a single datum by taking a weighted average of the individual values, using S_z^2 as weights. Similarly, six other pairs of closely spaced points were combined. The resultant Z_{TF}/S distribution is shown in Fig. 3. The χ^2 tests remain highly significant, but only 26 of the resultant 47 data have $r_{TF} < 0$, and $P(r > 26) \approx 23\%$, which is not statistically significant. Thus, based on the spread in the z_{TF} distribution and the results of the sign test, we conclude that the hypothesis that there is a historic negative correlation between local magnetic intensity and temperature trends is not statistically verified. The European data alone show an overall negative correlation significant at the

Fig. 3 The Fisher z transformation of the r_{TF} values of Fig. 1 divided by the standard deviations of the z distributions. Transformation of the raw values is given by Z_{TF}/S , while Z_{CTF}/S has combined values from stations in proximity to one another.

90% level, but because of the regional nature of the parameters, it would not be justifiable to conclude a causal relationship between intensity and climate.

Empirical studies of physical relationships are important for indicating appropriate lines of theoretical research. Although no proven theory links climate to geomagnetism, qualitative mechanisms have been postulated^{1,2,7,19}. These generally view the geomagnetic poles as flux tubes along which charged particles can propagate into lower regions of the atmosphere. Changing strength and orientation of the dipole field might then affect the quantity and geographic orientation of the ion corpuscular radiation⁷⁻⁹. However, it would be difficult to conceive of a mechanism that could link all local disturbances of the magnetic field to climatic change.

Because of the highly linear trends in magnetic field strength variation in many parts of the world, there will inevitably be some places where there will be an inverse relationship between the changes in temperature and the magnetic field. Without a viable physical mechanism that could produce such a relationship worldwide, we conclude that the weak, negative correlation between magnetic field strength and temperature in the historical record is a fortuitous result of the linear secular variation of magnetic field intensity and the poor geographic distribution of stations.

Detection of Ni-Sn phases in temper embrittled Ni-Cr steels

A GENERIC problem in ferritic steels is the reduction in the grain boundary cohesive strength produced by the segregation of trace impurities of Groups IVB and VB of the Periodic Table. Such segregation results in a deterioration in mechanical properties produced, for example, by reversible temper embrittlement¹ and it also promotes enhanced susceptibility to a range of environmental enhanced cracking processes²⁻⁴. It has long been recognised that the embrittlement of steels is enhanced by the

Table 1 Composition of Ni-Cr steels studied

presence of certain alloy elements, that is Ni, Cr or Mn, and measurements using Auger electron spectroscopy (AES)⁵⁻⁷ have demonstrated that specific combinations of alloy and impurity elements cosegregate to the boundaries, for example, Ni+Sn, Ni+Sb, Cr+P. These observations can be rationalised using Guttman's phenomenological theory⁸ which attributes the increased driving force for segregation to a positive interaction between alloy and impurity solute atoms. Previous investigations^{1,9-11} have failed to detect the presence of any three dimensional phase using conventional transmission electron microscopy and it is generally considered that the alloy element-trace impurity atoms form two dimensional phases at the boundaries. The only direct evidence for such alloy-impurity interactions and phase formation has been obtained using

Fig. 1 Micrograph of an extraction replica showing the precipitate distribution in En30A steel after ageing for 5,000 h at 500 °C. A convergent beam microdiffraction pattern of the Ni₃Sn phase is shown in the inset, (211) zone.

Fig. 2 Energy dispersive X-ray spectrum obtained from the Ni₃Sn phase indicating the presence of Ni, Mn, Sn and Sb.

Mössbauer spectroscopy^{12,13} but it is not possible using this technique to draw any positive conclusions regarding the location of such compounds. Measurements on a pure Fe-3.5 wt% Ni alloy doped with ¹¹⁹Sn¹² showed that Ni atoms associate preferentially with Sn atoms during tempering at 650 °C and the marked change in the spectrum observed on ageing at 500 °C, within the embrittling temperature range, is consistent with the formation of a Ni-Sn compound (Ni₃Sn₂ or Ni₃Sn₄). We report here some initial results from a detailed electron microscopic analysis of the microstructures of a commercial (En30A) Ni-Cr steel and a special laboratory made steel (BE 10) having similar Ni and Cr contents, but doped specifically with tin. The composition of the two steels is presented in Table 1. Both steels were oil quenched from 950 °C, tempered for 1 h at 650 °C and aged at 500 °C for times up to 5,000 h. Carbon extraction replicas, taken from polished surfaces were examined in a Philips EM400 microscope fitted with an energy dispersive X-ray system. Selected individual precipitate particles were analysed using convergent beam microdiffraction and X-ray analysis. Attention was focused on the particles which delineated the lath packet and previous austenite boundaries, that is, high-angle boundaries.

An electron micrograph showing the precipitate distribution in En30A after ageing for 5,000 h at 500 °C is presented in Fig. 1. The results from analysing the precipitates in the quenched and tempered condition and after ageing at 500 °C for times up to 5,000 h are listed in Table 2. For ageing times <100 h at 500 °C only orthorhombic Fe₃C particles, in which 10–20% of the iron is replaced by Cr, were identified. On ageing for 500 h at 500 °C the boundaries contained about 96% Fe₃C and 2% hexagonal M₇C₃ particles containing Fe and Cr in approximately equal amounts. In addition, about 2% of the particles were analysed to contain Ni and Sn and an example is arrowed in Fig. 1. Such particles were invariably located within small clusters of particles and were apparently attached to Fe₃C particles, although frequently M₇C₃ particles were also present in the clusters. The structure was analysed to be cubic with a lattice unit cell size of 0.598 ± 0.004 nm which matches a Ni₃Sn phase previously reported¹⁶ to be stable only above 950 °C. A (211) zone axis diffraction pattern is shown in the inset of Fig. 1. Two sections of the X-ray spectrum from a particle are presented in Fig. 2. It can be seen that the particles contain significant amounts of Sb and Mn in addition to Sn and Ni but no P was detected, although parallel AES studies¹⁴ have shown that P is present at the grain boundaries in significant amounts (~15 %). The copper K_α peak in the spectrum comes from the copper grid on which the replica was mounted. On ageing for 5,000 h at 500 °C the proportion of M₇C₃ and Ni-Sn precipitates increased to 15% and 5% respectively, the balance again being Fe₃C.

A more limited study was made of the high purity laboratory made steel, BE10, doped with 425 p.p.m. Sn (Table 1). An examination of the material aged for 5,000 h at 500 °C showed two significant differences from the ageing behaviour exhibited

by En30A. First, a higher proportion of M_7C_3 was present suggesting that the transformation from Fe_3C is occurring at earlier ageing times. Second, a Ni-Sn phase was again observed but was only found adjoining M_7C_3 particles. Results from microdiffraction and X-ray analysis were consistent with the phase being of the type Ni_3Sn_2 having a hexagonal superlattice structure. Thus, these results provide further support of the Mössbauer results¹² which were also obtained from a special laboratory made steel having a high Sn content.

In the present study, convergent beam microanalysis¹⁵ has been used to characterise individual particles as small as 20 nm diameter in terms of both structure and composition. This technique has enabled us to obtain the first direct evidence for the formation of discrete three dimensional intermetallic compounds from alloy and impurity elements in temper embrittled steels. The results indicate a dependence between steel composition, carbide transformation kinetics and the type of Ni-Sn phase formed and therefore caution is required in predicting the behaviour of commercial steels based on the results obtained from specially prepared casts. The present work demonstrates that careful microstructural characterisation provides an important insight into the processes contributing to grain boundary centred embrittlement phenomena.

Electron nuclear double resonance signals from three ingredients of coal

ELECTRON spin resonance (ESR) spectra from coals were first reported in 1954¹⁻³. Since then many ESR studies on coals have been conducted, and the signals have been shown to arise from free radicals^{4,5}. Recently Kevan *et al.* studied coals using the electron nuclear double resonance (ENDOR) technique⁶. They detected a single-peak signal at the free proton frequency, thus providing the first direct evidence that the environments of radicals in coals contain hydrogen atoms. We report here on ENDOR signals from three ingredients which were separated out from a coal sample. The ENDOR signal from each ingredient is substantially different from that of the other ingredients. In addition, a proton hyperfine structure (hfs) was experimentally resolved, probably for the first time, for a radical in one ingredient of a coal sample.

Fig. 1 ENDOR signals from three ingredients of a bituminous coal sample at a relative microwave power of -11 db. The signals were obtained for the out-of-phase mode⁸ at room temperature in air. The RF field was 8.2 G, which was measured by a sideband method¹¹. The free proton frequency was 13.5 MHz. a, Vitrain; b, clarain; c, fusain.

The sample studied was bituminous coal taken from a coal mine in Alabama. This sample showed three distinct layers—bright-glossy, satin-glossy and dull—composed of vitrain, clarain and fusain, respectively⁷. The coal sample was crushed into pieces of average size $0.5 \times 0.5 \times 1.0$ mm. Several pieces of each ingredient were then hand picked, and were put into a Teflon sample tube, which was designed to fit the ESR/ENDOR sample holder.

The ESR absorption from these ingredients showed only a small oxygen effect in intensity⁴. The radical concentration, which was measured using a DPPH probe, was comparable for the three ingredients: $4 \times 10^{19} \text{ g}^{-1}$ for vitrain, $4 \times 10^{19} \text{ g}^{-1}$ for clarain, and $3 \times 10^{19} \text{ g}^{-1}$ for fusain.

The ENDOR technique with an intense radiofrequency (RF) field⁸⁻¹¹ was used. The signal was detected at room temperature in the out-of-phase mode⁸ using an RF field of 8.2 G. Detection of the ENDOR signal was difficult when the RF field was below 3 G. No significant ENDOR signal was detected when the in-phase detection mode was used, even though the applied RF field was higher than 3 G.

The ESR signals from vitrain and clarain samples exhibited a maximum intensity at a relative microwave power of -11 db (-3 db for fusain samples), and the ENDOR signals from the three samples at -11 db are shown in Fig. 1. The signals are quite different for the three different coal ingredients. These spectra indicate that the environment of the unpaired electrons in each ingredient is substantially different from that of the other two.

The chemical compositions of the three ingredients are slightly different from each other⁷: the carbon content is highest and the hydrogen content lowest in fusain, while the content of volatile matter is highest in clarain. Thus it is possible that different ingredients contain different free radical species. Even if these radicals are chemically identical, the environment of the radical would differ from one ingredient to another. Note that the technique used here can effectively detect ENDOR signals from protons in the environment of a free radical¹⁰.

Furthermore, an out-of-phase ENDOR signal, such as that observed in the present case, is highly sensitive to the spin-lattice relaxation time⁸. Thus, it is quite possible that although the

radicals, including their environments, are chemically identical, different ingredients could give quite different ENDOR signals; this difference could originate from the difference in spin-lattice relaxation time, which is due to minor difference in structure deformation of the radical and/or its environment between different ingredients.

For these reasons the different coal ingredients might be expected to give different ENDOR signals. The nature of the difference in ingredients which is responsible for the difference in the ENDOR signals, however, is not yet clear.

The weak signal for fusain (see Fig. 1) can be attributed to an impurity. Examination of the specimen by a magnifier revealed a small bright region which appeared to be vitrain. Another specimen of fusain with a larger bright region showed a substantially stronger ENDOR signal.

Fig. 2 Signals similar to those in Fig. 1 but observed at a relative microwave power of -20 db. The relative amplifier gain was twice that for the case of Fig. 1. a, Vitrain; b, clarain; c, fusain.

The sharp central peaks of the ENDOR signals from both vitrain and clarain, as seen in Fig. 1, exhibited a line width and line intensity dependence on microwave power which was very similar to the ENDOR signal reported by Kevan *et al.*⁶ The line width of our central peaks (~0.4 MHz) increased appreciably at higher microwave powers. The intensity of these peaks was also very sensitive to microwave power, and at a relative microwave power of -20 db (see Fig. 2), no evidence for this central peak is seen in vitrain and in clarain. In fusain this peak is very weak. This type of single ENDOR peak has been detected previously in irradiated crystals⁶. This peak and the similar one from these coal samples result from RF-field-induced positive phase shifts of the modulated ESR signals. In contrast, ordinary hfs ENDOR signals arise from negative phase shifts. The mechanism for the appearance of these single peaks has not been clarified.

As is seen in the second curve of Fig. 2, the ENDOR spectrum for clarain shows three negative signals (shown by arrows in Fig. 2), arising from hfs splitting. The central signal arises from protons with very small hfs, and the other two from proton couplings with an average hfs splitting of 3 MHz. The latter splitting is probably the first resolved case of hfs in coals.

It is not clear whether the two positive peaks for clarain (starred in Fig. 2) are hfs signals. It is possible that these two peaks appear as a result of a superposition of the signal from a vitrain impurity. In another specimen of clarain, at a microwave power of -20 db the position of the bottom of the central signal (negative in Fig. 2) was higher and in the positive region. This could indicate a higher concentration of a vitrain impurity which, when combined with the central negative signal, could give rise to the two observed positive peaks.

The signal from vitrain was broad and positive (see Fig. 2). Note that vitrain is known to have five modifications⁷. Thus, it is possible that this specimen could be further separated into five or more ingredients.

This investigation was supported by a grant from the School of Mine and Energy Development, The University of Alabama.

Lignin-like polymers in coals

ALTHOUGH lignins are major constituents of plants from which coals are derived, their roles in the coalification process and resulting coal structures have not been defined. On the basis of chemical and biological degradations, lignins are considered to be polymers of *p*-coumaryl- (I), coniferyl- (II), and sinapyl- (III) alcohols¹⁻³.

Isolation of coal degradation products related to these three monomers should shed some light on the roles played by lignins during coalification and in the final structure of coals. To date such studies have had only limited success. Many oxidative degradations have also been carried out to break coal down into simpler species; however, isolation and identification of *p*-hydroxyl (IV), vanillyl (V), and syringyl (VI) groups, which are characteristic lignin oxidation products, have not yet been confirmed.

R = -CHO, -COCH₃, or -COOH; X = H or CH₃

Table 1 Summary of CuO–NaOH oxidation of coal*

Wt % of products†	Lignite	Bituminous
Organic acid (benzene–ether extract)	35.3	19.6

* Elemental analysis (dry ash free basis): Lignite (Wyoming) C, 66.4; H, 4.7; N, 1.5; S, 1.1; O, 26.3 (by difference). Bituminous (Illinois #2) C, 73.9; H, 5.2; N, 1.4; S, 2.4; O, 17.1 (by difference). Anthracite (Pennsylvania PSOC 85) C, 91.0; H, 3.8; N, 0.7; S, 1.2; O, 3.3 (by difference). Samples were pretreated to remove solvent extractable trapped organic materials before analysis.

† Wt % was obtained from sample on a dry ash free basis.

‡ Wt % was obtained from each benzene–ether extract and the amount of each compound determined from GC.

§ Aromatic aldehyde, keto and unidentified compounds.

We report here that, using a CuO–NaOH oxidation procedure we were able to isolate phenolic acids which show a relationship between lignins and coals.

Although fulvic and humic acids^{4–6} have been degraded successfully with alkaline solutions to produce lignin-related phenols, this method has not been successful in coals^{7,8}. Reductive degradations of soil⁹ and coal-derived¹⁰ humic acids with sodium amalgam have been reported to produce a variety of phenolic compounds; however, the method used has been criticised because of its poor yields and its being so drastic that resulting chemical structures may have little or no relation to the starting material^{11,12}. In general, commonly used oxidants destroy phenolic rings or give complex products^{13,14}. Some of the oxidants such as nitrobenzene produce reaction byproducts that may interfere with the analysis of the oxidation products^{15–17}. To obtain lignin oxidation products from coals we used the alkaline cupric oxide oxidation method which has been successfully applied to analysis of lignins in plants¹⁵, humic acids^{17,18} and land-derived marine sediments¹⁵. To obtain detailed information of the CuO–NaOH oxidation, control experiments with known phenols, phenyl alcohols, aryl alkyl ethers and alkyl benzenes were also carried out using the procedure employed for the coals.

After removal of trapped organic compounds^{19,20}, 5 g of each coal sample (lignite, bituminous and anthracite, see Table 1) was oxidised with alkaline cupric oxide (52 g of CuSO₄ · 5H₂O, 37 g of NaOH and 185 ml of H₂O) at 200 °C for 8–10 h by the method of Greene *et al.*²¹. After separation of insoluble residue, the alkaline solution was acidified with HCl. The acidic solution was concentrated and extracted repeatedly with benzene–ether (1:3) and finally with methanol. Yields of the oxidation products from lignite and bituminous coals are shown in Table 1. No organic solvent-extractable oxidation product was isolated from anthracite coal. The benzene–ether extracts were derivatised with d₆-dimethylsulphate to yield d₃-methyl labelled derivatives. The derivatives were analysed by gas chromatography–mass spectrometry (GCMS) and high resolution MS using techniques described previously¹⁹. The retention times and mass spectra of the phenolic esters were confirmed with authentic samples. Gas chromatograms of the derivatives are shown in Fig. 1 with numbered peaks identified in Table 2. The methanol extracts from both coals were found to consist essentially of humic acid-like material soluble in alkali but complex and of high molecular weight^{3,22,23}.

As shown in Fig. 1 and Tables 1 and 2 the identification of large amounts of *p*-hydroxy- and 3,4-dihydroxybenzoic acids which are regarded as characteristic lignin oxidation products is very informative. Phenolic di- and tricarboxylic acids, and hydroxynaphthalenecarboxylic acids were also identified which are not obtained from land plants¹⁵ and marine sediments¹⁵ by the same oxidation.

All phenolic acids identified were found as OCD₃-derivatives. The mass spectra showed the complete absence of OCH₃-group. It is confirmed that no isotope exchange of the H in OCH₃ with D occurred during our procedures. Although partial demethylation reaction during the oxidation cannot be excluded from the control experiment, it is probable that the phenolic acids found were derived mainly from the fission of ether-linked aromatic systems as shown in the example below rather than from aryl methoxy units.

Indeed, it is known that very little or no methoxy groups are present in bituminous coals^{23,24}. In the lignite coal aryl methoxy groups are probably not present in significant amounts.

Trihydroxybenzoic acids (syringic group) were not found in the oxidation products. We have found that the authentic syringaldehyde was largely degraded by the oxidation. This may account for the fact that we did not observe them; however, the syringic group may have been degraded during coalification. Authentic mono- and dihydroxybenzenes were found to be stable in the same conditions.

Non-hydroxy substituted benzene-, naphthalene-, pyridine-carboxylic acids and humic acid-like materials found might be

Fig. 1 Gas chromatogram of methyl esters of the organic acid fraction from lignite (a) and from bituminous coal (b). The analysis was carried out on a Perkin-Elmer 3920B gas chromatograph interfaced to a modified Bendix model 12 time-of-flight mass spectrometer with a variable split between a flame ionisation detector and the source of the mass spectrometer. The separation was made on a 15.2 m $\times$ 0.51 mm SCOT column coated with OV17 and temperature programmed from 100–250 °C at 4 °C min⁻¹.

derived from non-lignin or extensively transformed lignin polymers. It is obvious that extensive transformation of lignin-like polymers occurred through several reactions^{22,25} such as demethylation, demethoxylation, dehydrogenation, oxidation, cleavage of ring structures and re-condensation during coalification from lignite to bituminous and anthracite coals. Indeed, we have observed that the CuO–NaOH oxidation of higher rank coals (C, 78–87%) produces very little phenolic acid with an increased yield of non-hydroxy aromatic and heterocyclic acids (data not shown).

Previously²⁰ we characterised aromatic acids trapped in lignite coal, and have found that these acids are qualitatively quite similar to those obtained from the present oxidation of the same pretreated coal. This indicates that the trapped acids were derived mainly from the hydrolytic oxidative degradation of lignin-like polymers during the coalification. Indeed, the later coalification product, the anthracite coal, did not give any trapped acid²⁰ or organic solvent-soluble CuO–NaOH oxidation product. Flaig has also discussed²² oxidative transformation of plant material during humification and coalification.

Our results show that lignin-like polymers are incorporated into the macromolecules of lignite and bituminous coals. It is indicated that the polymers contain more highly cross-linked structures with increased aromaticity compared with the original lignins. This is experimentally shown by the identification of phenolic polycarboxylic acids and hydroxynaphthalene-carboxylic acids which are not found in the CuO–NaOH oxidation products of lignins and plant materials. In addition, plant polyphenols other than lignin could also be precursors for coal formation.

Fluctuations in SO₂ emission during recent eruptions of Etna

THE eruptive activity of July–August 1977 of Mt Etna consisted of four separate, short eruptive episodes: 16–22 July; 5–6 August; 14 August; 24 August. The rate of SO₂ emission during these eruptions was monitored using a remote-sensing correlation spectrometer. These data suggest that fluctuations in the SO₂ emission rate provide a means for predicting eruptions of Etna.

The July–August 1977 eruptions were confined to the North East Crater vent, while continuous degassing occurred from the central vents. The continuous gas plume was blown downwind immediately after it was emitted while the eruption plumes from the North East Crater rose 500–1,000 m before being blown horizontally. As the plumes moved downwind they were maintained at elevations ranging from 2,000 to 3,000 m above sea level. Monitoring began on 24 July, immediately after the first eruptive episode had ended, and continued until 27 August.

A Barringer Correlation Spectrometer (COSPEC) was used to monitor the SO₂ in the volcanic plume. (The application and design principles have been described by Newcomb and Millán¹.) The spectrometer consists of a Cassegrain telescope, a

Fig. 1 A typical SO_2 plume cross-section obtained with the COSPEC mounted in an automobile. The instrument is calibrated at both ends of a traverse. The large calibration represents 370 p.p.m. m while the small calibration represents 125 p.p.m. m. The abscissa of the curve is time. A single traverse took ~ 15 min.

grating spectrometer, a correlator disk, and processing electronics section. Incoming radiation is dispersed by the spectrometer. The correlator disk then alternately passes UV spectra of high and low SO_2 absorption. This modulated signal is monitored by photomultiplier tubes which produce a voltage that is processed by the electronics. This processed voltage is proportional to the number of SO_2 molecules in the field of view of the instrument. This is a concentration-pathlength value and has dimensions in parts per million metres (p.p.m. m). The response of the instrument is calibrated by reference cells filled with known concentrations of SO_2 . The instrument also has an automatic gain control to compensate for changes in the radiation source (the daytime sky).

Data reported here were gathered with the COSPEC mounted in a vehicle with a right angle mirror attached to the telescope to allow a vertical field of view. The vehicle was driven under the plume approximately perpendicular to the plume direction. Concentration-pathlength data from the COSPEC are recorded on a stripchart recorder along with odometer readings to provide a distance scale. Instrument calibrations were done before and after each traverse so that instrument drift could be checked. Figure 1 shows the record from a single traverse.

The area under the concentration-pathlength-distance curve represents a SO_2 cross-section of the plume (p.p.m. m^2). This value is corrected for traverses that are not at right angles to the plume direction. A mass flow of SO_2 (tonnes d^{-1}) is calculated by multiplying the p.p.m. m^2 value times the horizontal wind speed of the plume (m d^{-1}) times the density of SO_2 gas (tonnes per p.p.m. m^3).

The traverses were made on the roads shown on Fig. 2. The arrow from the summit shows the average wind direction for the period of this study, while the range of the wind direction

Fig. 2 Map of the roads used to obtain traverse data. The large arrow from the summit represents the mean wind direction while the smaller arrows represent the range of the wind directions.

for the period 16 July–28 August 1977 is shown by the shorter arrows. The roads are all between 7 and 10 km from the summit, and between 1,000 to 2,000 m below the plume as it passed overhead.

Two to eight traverses were made per day. A mass flow value was calculated for each traverse and the values from a given day were averaged to give a mean mass flow value for that day. Cloudy weather (clouds reduce the UV intensity and increase the instrument noise) or equipment failure account for missing days of data.

The activity of Mt Etna during July and August 1977 allowed the measurement of SO_2 output before, during, and after eruptive activity of the volcano. The SO_2 mass flow data are plotted

Fig. 3 SO_2 mass flow averages for the period of study. The dotted lines connecting the SO_2 data points are periods with missing days of data. The bars through each data point represent 1 standard deviation of the daily average. The bar graphs represent qualitative estimates of summit activity.

in Fig. 3. The SO₂ fluctuation curve is a plot of SO₂ mass flow (tonnes d⁻¹) versus time (16 July–28 August 1977). The bars through the points equal one standard deviation of the daily data. These should not be interpreted as error bars, but, rather an indication of the natural fluctuation of the volcano for a given day. The observed summit activity categories are meant only as qualitative estimates of the actual summit activity. The dotted lines connect intervals where there were missing days of data.

The data from 25 July to 1 August established a baseline level of ~1,000 tonnes d⁻¹ for SO₂ mass flow during non-eruptive periods. The traverses made on the morning of 5 August showed SO₂ levels up to 3.3 times the 1,000 tonnes d⁻¹ baseline value (1,830–3,330 tonnes d⁻¹). At 14.20 on the same day an eruption began in the North East Crater. Continued monitoring during the eruption showed that the SO₂ levels were above 5,000 tonnes d⁻¹.

By the morning of the 6 August, the activity had ceased and the SO₂ emission dropped to below the 1,000 tonnes d⁻¹ baseline level. The mass flow apparently remained constant until the 10th when a gradual increase began which continued through the 12th. Due to poor weather, the SO₂ levels were not measured on the 13th. At 03.00 on the 14th, the third eruptive phase began with SO₂ levels during the day again above 5,000 tonnes d⁻¹. By the evening of the 14th, the eruption had ceased and SO₂ levels on the 15th returned to the 1,000 tonnes d⁻¹ level.

SO₂ emissions from 15 to 24 August gradually increased to fairly high levels. The 4,000 tonnes d⁻¹ average on the 24th was accompanied by a small lava flow within the North East Crater, but no explosive activity occurred as in the previous eruptions. Monitoring ended on 27 August, with the SO₂ levels still fairly high. However, no further activity was observed until December 1977.

The SO₂ mass flow values reported here are all minimum values. Three factors combine to reduce the measured SO₂ value. These factors are signal attenuation, plume opacity and loss of SO₂ by reaction to SO₄. The COSPEC is a pathlength dependent device. As the distance between the plume and sensor increases, the measured SO₂ values decrease. This has been described by Moffat and Millán² in studies of powerplant plumes. Increasing plume opacity also tends to reduce the measured SO₂ values. This has also been documented in powerplant plume studies³. This factor is important to consider during eruptive activity when there is an increase in pyroclastic material in the plume. A third mechanism for SO₂ signal reduction is the reaction of SO₂ to SO₄, in water droplets in the plume. The COSPEC 'sees' only SO₂ therefore, SO₂ converted to SO₄ is effectively lost. The fact that these values are minimums does not reduce the validity of the SO₂ fluctuation curve since the mass flow averages were all obtained using the same technique, at equal distances from the vent, and at equal vertical distances from the plume.

It is evident that the increases in the SO₂ mass flow from Mt Etna could possibly be used as premonitory signs of impending activity. Two possible types of increases are suggested. First, the sharp increase such as before the 5 August eruption. Second, the gradual increase as exemplified by the periods 9–12 August, and 15–24 August.

The SO₂ mass flow variations correlate well with a model for the movement of magma within the conduit system at Etna proposed by Wadge⁴. He suggests that the eruptive pattern of Etna begins with filling of the conduit system. Activity is initiated by summit eruptions which are followed by flank eruptions. After the flank eruption drains the conduit system, the eruption ends and the cycle begins again. The SO₂ emission levels directly reflect the different levels of the magma.

In theory similar patterns should exist for all volcanoes. As the magma rises, SO₂ gas will be released in greater quantities. One should be able to monitor this increase. The absolute values for mass flow will vary from volcano to volcano, and possibly from eruption to eruption. The time fluctuation between observed

SO₂ increase and eruptive activity could be either compressed or extended.

Previous studies of condensates from high temperature fumaroles adjacent to main volcanic vents^{5–7} has long suggested that the SO₂ volume or S/Cl ratio increases before eruptive activity. The technique of remote sensing by correlation spectrometer provides a simpler and safer method for monitoring the SO₂ emission from the main vents of a volcano.

Several investigators have measured the SO₂ emission from various volcanoes^{8–12}. These data are in the same range as the data collected at Mt Etna, however, much more data are needed from individual volcanoes to determine the range of SO₂ emission and time period fluctuations. Given sufficient data, patterns might become well enough established to allow prediction of eruptions based on SO₂ fluctuations.

Intra-plate deformation: a quantitative study of the faults activated by the 1978 Thessaloniki earthquakes

THE Thessaloniki region suffered from damaging seismic activity during the summer of 1978. During both major shocks that took place on the 24 May (*M*, 5.5) and 20 June (*M*, 6.5), manifestations of faulting could be observed in the epicentral areas. They showed that the continental crust is stretching out in this region. Measurement of slips on the active faults make it possible to compute the direction of traction (165° N) in the crust. These active faults show close kinematic similarities to previously neotectonically defined faults of Recent Quaternary age (after 400,000 yr) within the same region. Thus, study of Recent neotectonic faults often gives a correct prediction of the direction of possible slipping on faults which could be activated by earthquakes in the same region. We show here that a quantitative study of active and neotectonic faults demonstrates that in this intracontinental situation faulting deformation is satisfactorily explained with a model of continuous deformation.

The epicentral region is made up of a graben (Fig. 1) which demonstrates the presence of recent extensional tectonic activity in this area^{1,2}. An examination of the LANDSAT 1 satellite photographs (Fig. 1) indicates that this angular crank-shaped graben probably results mainly from sinistral wrench movement along NW–SE orientated fault zones. In addition opening occurs along normal faults of E–W to ENE–WSW directions. Similar movements have been observed, SW and SE of the Langadha Lake, on neotectonic faults which have a post Middle Pleistocene age³.

The faults that were formed during both 1978 earthquakes (Fig. 2) confirm this structural setting. Open cracks with an

oblique shear component, having centimetre-sized openings, have been observed in unconsolidated sediments of Upper Miocene-Pliocene and Quaternary ages. These cracks have a shear movement which is essentially dip-slip along planes which strike between 060° N and 090° N (maximum downthrows of 20 cm, see sites 32, 33 and 16 in Fig. 2) or sinistral strike slip (maximum displacements of 10 cm, see site 17) but have an important vertical component along faults striking between 110° N and 130° N. On the other hand, in bed-rock composed of Palaeozoic mica schists (sites 10, 11, 13, 15, 30, 35) the faults contain striations along their shear planes and these have a clear tectonic origin.

These faults and cracks are distributed throughout the epicentral zone and apart from some typical gravitational slide-failures (sites 23 and 26), they are located within Plio-Quaternary fault zones (Fig. 2) which have obviously been reactivated during the 1978 earthquakes.

Numerous cracks observed in unconsolidated sediments appear as small reverse faults. This could have been wrongly interpreted in terms of a compressional mechanism. Slip movement on the active fault plane only takes place where a required overburden pressure is reached (Fig. 3). In the shallow unconsolidated sediments, the motion is made possible by the opening of a curved crack the dip of which can be overturned at the surface. Thus the slip along the normal fault at depth manifests itself on the surface by a crack that has an apparent reverse fault geometry (Fig. 3). All the observed fault planes have a normal faulting component which corresponds to an active extensional tectonic activity.

Along the fault planes affecting the bed-rock, the slip vector corresponds to a frictional striation which can be exactly measured. In unconsolidated sediments of sufficiently rigid quality, the cracks at the surface yield the slip vector for the deeper active fault. This slip vector is equal to the displacement joining two points of contiguous origin being presently at opposite position across the open crack (Fig. 3).

Open cracks could have been wrongly interpreted in terms of gravitational sliding. In such a case, slip-vectors have to be parallel to the steepest slope of the cracks which means that $\theta_w \propto \alpha_{FP}$ (Fig. 4). This linear relationship gives the straight line in Fig. 4. The data, represented by dots, do not agree. The azimuths of the slip vectors lie between 300° and 30° N or

between 140° and 210° N. These two bands are in opposite position on the stereonet; in other words, the cracks cannot have a gravitational origin.

Figure 2 shows that the faults striking between 110° and 130° N have a sinistral-normal behaviour; those between 060° and 090° N are essentially normal and those between 015° and 040° N are also strike-slip but dextral-normal. These faults which are regionally scattered and which have a variable strike direction are a demonstration of the extent of the regional deformation which has taken place.

Regional deformation occurs through finite slip along existing fault planes in a highly fractured medium. In this situation, a model of continuous deformation ought to be tested. The slip $\vec{S}$ on the fault plane has to be parallel to the tangential component $\vec{\tau}$ of the applied stress. The orientation of $\vec{\tau}$ is only function of the orientation of the principal axes and of the ratio $R = \sigma'_1 - \sigma'_3 / \sigma'_2 - \sigma'_3$, where the σ' are deviatoric stresses⁴. Also the knowledge of the slip vectors $\vec{S}$ corresponding to a given family of faults can lead to the determination of the above parameters⁵. The computation searches for the parameter values which minimise the deviation between the predicted striations $\vec{\tau}$ and the observed striations $\vec{S}$ for all the fault planes. Four of the planes would be sufficient to compute a solution. The numerical procedure minimises the function $F = \sum_{k=1}^N (\vec{\sigma}'_k \cdot \vec{u}_k)^2 / |\vec{\sigma}'_k|^2$ where $\vec{\sigma}'$ is the deviatoric stress acting on the fault plane, $\vec{u}$ the vector in the fault plane at right angle with the striation $\vec{S}$, and N the number of observed faults. Such a calculation was performed using only the most accurately measured slip vectors namely 10 bed-rock data from sites 10, 13, 15, 35 and from an additional site close to the sea, as well as three unconsolidated sediment data from sites 16, 22 and 23. This computation shows that the kinematics of active faults is best explained by a horizontal tension σ'_1 of azimuth 165° N. The intermediate stress σ'_2 is compressive, although of much smaller magnitude than σ'_1 and σ'_3 ; its orientation is horizontal with azimuth 76° N. This result gives a deviation between the observed $\vec{S}$ and predicted $\vec{\tau}$ which remains less than 15° . The situation is almost as satisfactory if the computation includes the other eight data from sites 2, 8, 17, 22, 32, 33, also in unconsolidated sediments but of lesser quality. Thus intra-continental tectonics can be satisfactorily analysed in terms of a continuous deformation model. This is because the geological material often contains numerous zones

Fig. 1 Structural map of the epicentral zone: lineaments observed from LANDSAT 1 pictures (thin lines), seismic and neotectonic faults described in this study (thick lines), graben of the Langadha (L) and Volvi (V) lakes (shaded area). Inset, the Wulff stereonet (lower hemisphere) shows the Quaternary fault (KA) to south-west of Langadha Lake and the major seismic fault (TH) with corresponding principal axes. Computed tensional directions are seen to coincide; black, white and T arrows correspond respectively to 1978 faults, Upper Quaternary faults and regional earthquake mechanisms.

Fig. 2 Detailed map of the epicentral region: lineaments and faults observed on aerial photographs (thin lines), 1978 faults and cracks (thick lines hatched on the side of downthrows). Numbered stars refer to studied sites. Corresponding stereonets illustrate: the strike (S) and the dip (D) of faults, the pitch (p) of the slip-vector (angle between the striation and the horizontal in the fault-plane), the vertical (VD) and horizontal (SD) components of the displacement (D). The arrowhead outside the circles indicates slip-vector orientation while the dot on the trace of the fault plane represents the slip vector, the attached arrow indicating the motion of the upper block. Letters are for the villages of Yerakourou (Y), Nikomedion (N), Stivos (St), Skolario (SK) and Peristeronas (P).

of weakness. A striking feature of our analysis appears in the stereonet in Fig. 1; the tensional direction σ'_1 (thick black arrow) deduced here is compatible with the tension (thin arrow marked T) deduced from regional focal mechanisms^{2,6-8}.

A fault system postdating Middle Pleistocene forms the SW edge of the Langadha Lake graben (Fig. 1). The faults of direction 130° N are normal with sinistral strike-slip³; they have not moved during the 1978 earthquakes. The neotectonic slip-vectors on the various fault planes are compatible with a deviatoric stress tensor very similar to the one obtained for the active faults. In particular, the corresponding tension axis σ'_1 (thick white arrow on the stereonet in Fig. 1) lies close to the tensional orientations described above. Another fault zone (site 35, Fig. 2) was studied before the earthquakes; it was active this time (Fig. 3). The faults are normal with dextral strike slip and the 1978 slip vectors are of similar orientation as those corresponding to earlier motions.

About 500 m to the north of site 35, along the same fault zone, the bed-rock exhibits a mylonite structure in which the fracture planes often contain two different superposed sets of striations. Here the kinematics are quite different from those of recent and active faults; this implies a tension σ'_1 along 120 – 130° N. The faults are probably younger than Mio-Pliocene but older than the Recent. These remarks indicate that only recent neotectonic features can be used to picture the present day active tectonics. It means that, for the region under study the regional stress field has not changed much during the recent period, probably Upper Quaternary, and that the material has not suffered much rotational deformation.

The analysis of ground motions during the last Thessalohiki earthquakes as well as the study of neotectonic data for Upper Quaternary faulting^{3,9} justify the use of models of continuous

deformation to account for intracontinental tectonics. This applies to strains of small magnitudes and hence short geological time periods. The integration over a longer time will give large scale continental deformations which can also be seen in terms of continuous deformation. Such an approach with the use of slip-lines has already been suggested¹⁰. For the Aegean region, the slip corresponds essentially to the dextral strike slip faults of

Fig. 3 Field view of the active Nikomedion fault (site 35 on Fig. 2), sketched after visual observation of a subvertical erosion surface. Insets show detailed slip vectors.

Fig. 4 Fault plane plotted against slip-vector azimuths for all investigated faults (○) and cracks (●). The stereonet clarifies the parameters. Only faults and cracks striking between 060° N (240°) and 090° N (270°) have a slip vector parallel to the steepest slope. Thus the corresponding dots lie on a straight line of slope 1.

NW Anatolia and to the sinistral faults of Macedonia^{3,11}. The deformation is, however, not purely planar so that extensive graben formation^{2,3} occurs near Thessaloniki.

We thank Drs McKenzie and G. King for discussion in the field. This work was supported by the Greek Ministry of Public Works through the Institute for Geology and Mining Research.

A doughnut-shaped pattern of seismic activity preceding the Shimane earthquake of 1978

AN earthquake occurred inland at shallow depth in Shimane, southwestern Japan (Fig. 1), on 3 June 1978 GMT. Its seismic magnitude was estimated as 6.1 by the Japan Meteorological Agency (JMA), which was larger than the body wave magnitude of 5.1 estimated by the US Geological Survey, (USGS). Some damage to construction was caused in the epicentral region. We show here that the doughnut-shaped active area and seismicity gap in its centre immediately preceding the earthquake indicated its region and likely magnitude.

The possibility of an earthquake occurring was inferred from the following reasons. First, the sequence of earthquakes during the past 50 yr suggested that a major earthquake with magnitude about 5 might occur in this region within a few years* (S. Asano, personal communication). Figure 2 shows that major events with magnitudes about 5 took place successively during 1950–55 and 1963–66. After a 10-yr quiescent period, an earthquake of $M = 5.3$ (JMA) occurred on 1 May 1977, adjacent to the focal region of the most recent event of $M = 6.1$. Considering that the active-inactive periods had already occurred twice in this region, the $M = 5.3$ event was suspected to indicate the onset of another seismically active period for a few to several years.

Second, the aftershock activity of the $M = 5.3$ event in 1977 had reached a new stage. Locations of the aftershocks of the $M = 5.3$ event had been limited to a small area until the autumn of 1977 when the microseismically active area started to spread into the adjacent areas (Fig. 3). Slight activity took place in the area north-west (October–November), east (November–December) and south (January–February) of the $M = 5.3$ event. Furthermore, from the beginning of 1978, the activity extended southwestwards to a somewhat broader area. No earthquakes had been observed in that area during the preceding half year. Although such changes in microseismicity do not always represent the possibility of the occurrence of a major earthquake, the fact that this region had entered a new stage in seismic activity may be significant from the viewpoint of earthquake prediction. For example, some of the major events of the Matsuhiro earthquake swarm in 1965–67, central Japan, were preceded by the spatial extension of microseismicity².

Fig. 1 Location of the $M = 6.1$ (larger circle) and $M = 5.3$ (smaller circle) earthquakes which occurred on 3 June 1978, and 1 May 1977, respectively. Crosses show the seismograph stations of the Shiraki Microearthquake Observatory (SHK, MKW and NKR) and the temporary stations (A and B) installed just before the $M = 6.1$ event. The area enclosed by the broken line is referred to in Figs 2 and 4.

Third, a doughnut-shaped pattern in microearthquakes had become apparent over a period of 5 months (Fig. 4). The microearthquakes which extended over the area south-west of the focal region of the $M = 5.3$ event had formed a doughnut-shaped active area and had left a circular aseismic area in its centre, suggesting a future earthquake, because such a pattern of seismicity had been seen before several other large earthquakes^{3,4}. The aseismic area was about 6 km in diameter. The extension and duration of this seismicity gap were considered to be too small for an event of $M = 7$ and probably 6, but large enough for a $M = 5$ event^{5,6}. The $M = 6.1$ event actually filled

Fig. 2 A sequence of major earthquakes ($M > 4.5$) occurred within the area shown in Fig. 1 during the past 50 yr (data recorded after the Japan Meteorological Agency).

this seismicity gap, although the principal rupture seems to have started within the doughnut-shaped active area.

These seismological data which suggested the possible occurrence of major earthquakes were presented to the Coordinating Committee for Earthquake Prediction, Japan. The earthquake sequence of the last 50 years in this region was reported by JMA in the 37th committee, which was held in May 1977, just after the $M = 5.3$ event. After the aftershock area of this $M = 5.3$ event began to expand, the Shiraki Microearthquake Observatory reported this to the 40th and 41st committees in February and May 1978, respectively. These reports did not explicitly predict a major earthquake because of the lack of successful predictions in Japan.

Fig. 3 Map of recent seismic activity around the focal region of the $M = 6.1$.

Fig. 4 Epicentral distribution of recent microearthquakes (left) and their superposition from August 1977 (right), in the 30 km $\times$ 30 km area shown in Fig. 1. Their magnitude was greater than about 1 and most of them were shallower than 10 km in depth. The bottom figure shows the aftershock area of the $M=6.1$ event during 0–2 a.m. on 4 June. The open circle represents the location of the seismicity gap.

Because of this anomalous seismic activity, we carried out temporary observations with seismometers enclosing the area of the seismicity gap from 5 to 2 days before the $M=6.1$ event. The temporary stations A (29 May–1 June) and B (30 May–1 June) are shown in Fig. 1. During this period, no events greater than about 0 in magnitude were observed in either the aseismic area or the doughnut-shaped active area. No events greater than about 1 in magnitude were also observed by the local network of the Shiraki Microearthquake Observatory until the $M=6.1$ event occurred on 3 June. Thus, the focal region of the $M=6.1$ event seems to have remained fairly inactive for several days just before the main shock.

The present $M=6.1$ Shimane earthquake was preceded by anomalous seismic activity in both time and space. A doughnut-shaped active area and a seismicity gap in its centre were apparent 5 months before the $M=6.1$ event. This suggested the location and the magnitude of the impending earthquake. The actual magnitude ($M=6.1$, JMA) was larger than expected ($M=5$). But a lesser magnitude ($M=5.1$) was also presented by USGS. The low activity around the focal region for several days just before the main shock, which was determined by the temporary observations, might have represented the imminent outbreak of the $M=6.1$ event. The microseismicity preceding the present event may be of interest as a way of predicting earthquake occurrence.

We thank Professor Kazuaki Nakamura, Drs Paul Somerville and Kunihiro Shimazaki for critical comments, and Professor Shuzo Asano for encouragement.

Parallel changes in species diversity and palaeotemperature in the Lower Miocene

OXYGEN isotope analysis of planktonic foraminifera from 12 samples of deep-sea sediment of Lower Miocene age has been performed to estimate the sea-surface temperature at that time, and the results are reported here. The samples were taken from a borehole in the English Channel, 110 km south-west of the Isles of Scilly¹. The planktonic foraminifera have already been described in detail¹ and it has been shown that the fauna is from the Lower Miocene Burdigalian *Globigerinoides trilobus* zone. Comparison with samples of the same age from New Zealand suggests sea-surface temperatures in the range 16–20 °C or warmer, on the basis of oxygen isotope determinations in New Zealand² and on the presence in the present samples of *Globigerinoides sacculifer* (Brady). It has also been suggested from previous palaeoecological work on foraminifera of the Western Approaches, that there was only a small difference between the Miocene and present-day sea-surface August temperatures (which are 15–18 °C)³.

In the ocean both plankton tow⁴ and isotopic⁵ data suggest that *G. sacculifer* inhabits surface water and is therefore a suitable species to analyse for the estimation of isotopic palaeotemperatures. Specimens were selected from the samples

Table 1 Oxygen and carbon isotope data for *Globigerinoides sacculifer* (Brady) from the borehole

examined by Jenkins¹ and roasted *in vacuo* at 400 °C for 30 min before isotopic analysis, to volatilise possible organic contaminants. Carbon dioxide was generated by the action of orthophosphoric acid at 50 °C and analysed isotopically in a VG Micromass 602C mass spectrometer⁶. Overall reproducibility of the measurements is about $\pm 0.1\%$ (1σ). Measurements of δ_c (Table 1) have been converted to sea-surface temperatures assuming an oxygen isotopic composition δ_w for the Lower Miocene ocean, before the accumulation of the Antarctic ice sheet, of -1.2% on the PDB scale⁷. Although there is some uncertainty in the temperature derived using this estimate it probably does not exceed one or two degrees and is unlikely to contribute to the variability among the estimates. Temperatures were estimated using the temperature- δ relationship: $T = 16.9 - 4.4(\delta_w - \delta_c) + 0.1(\delta_c - \delta_w)^2$ (refs 8, 9). Figure 1 shows error bars corresponding to ± 2 standard deviations; these do not take account of possible systematic errors which would not contribute to the observed temperature changes within the sequence.

**Fig. 1** Measurements of palaeotemperature and species diversity of planktonic foraminifera in the Lower Miocene Sea Lab Trial borehole from the English Channel.

The isotope measurements (Fig. 1) show an estimated temperature range from 15.5 to 21.5 °C, with lower temperatures in the *G. semivera* subzone and higher in the succeeding *G. praescitula* subzone. Elsewhere *Globorotalia praescitula* first appears before the *G. trilobus* zone¹⁰ so that its local appearance in the English Channel may have been controlled by temperature.

Figure 1 shows species diversity of planktonic foraminifera¹ as well as temperature. In today's ocean there is a definite relationship between species diversity and temperature⁴ although other factors contribute to diversity patterns. Previous work has shown a broad correlation between species diversity and oxygen isotope palaeotemperature in the New Zealand Cainozoic^{11,12} but the comparison was done on the basis of total diversity of a section rather than on the diversity in individual samples. Figure 1 shows a remarkable detailed relationship between diversity and isotopic palaeotemperature among the individual samples studied.

Over geological time, species diversity is obviously likely to be controlled by evolutionary processes¹², as well as by changes in the competitive balance between different faunal groups. However, in the present situation we are studying changes within a single zone, and perhaps only over an interval of about a million years, so that neither factor is likely to contribute to varying species diversity. In this circumstance it is perhaps not surprising that the relationship between diversity and temperature is so clear. It is, therefore, of considerable interest because it opens up the possibility of estimating short-term changes in temperature in situations where the physical method of estimating palaeotemperature cannot be applied.

We thank M. A. Hall for operating the V. G. Micromass mass spectrometer on which the isotopic analyses were made; the work was supported by an NERC grant.

Two separate photoreceptors control hypocotyl growth in green seedlings

PHOTOCONTROL of elongation growth has been extensively studied in dark-grown (etiolated) seedlings for some time. However, only relatively recently has detailed attention been given to green (de-etiolated) plants. One reason for this is that the photoreceptor, phytochrome, can easily be detected spectrophotometrically in non-green tissues but not in tissue containing chlorophyll. There is agreement that the photoreceptor operates in its low-energy mode (low irradiances or fluence rates, with red/far-red reversibility) in green seedlings as well as in dark-grown, non-green seedlings. In its high-energy

Fig. 1 Growth kinetics in response to illumination and darkness. *a*, Blue-light inhibition and recovery: blue light was provided by an opposed pair of collimators (to prevent phototropism) focused on the 5-mm region of the hypocotyl measured ~10 mm from the cotyledonary node. The light source consisted of 150-W quartz-halogen bulbs in projectors, and the light from each was passed through a layer of Cinemoid (deep blue no. 20) and 30 mm of 2.5% cupric chloride (to eliminate far-red) and an additional lens for focusing. This combination gives broad-band light, from 400–510 nm (peak 440 nm; half-band width ~45 nm). (Fluence rate as in Table 2.) *b*, Red light inhibition and recovery. Diffuse red light was provided by light from 20-W Gro-lux fluorescent tubes filtered through a layer of Cinemoid (ruby red no. 14). This combination gives broad-band red light from 600–710 nm (peak 660 nm; half-band width ~20 nm). (Fluence rate as in Table 2—saturation is given by ~1 W m⁻².) Crosses mark the growth rate of dark control seedlings (having had a similar pretreatment). Each cross represents the mean growth rate for a 4-h period, the limits of which are shown by the horizontal bar (measurements by ruler, $n = 12$).

mode (high irradiances and time dependency), exemplified by the action of prolonged irradiation with far-red, phytochrome might act only in etiolated seedlings¹⁻³. Photoregulation of stem extension in etiolated and de-etiolated seedlings is also achieved by blue light (400–500 nm), but it is still not clear if a photoreceptor other than phytochrome is responsible for this effect. Kinetic studies on etiolated seedlings suggest the operation of a separate blue-responsive photosystem². Notwithstanding this, it has recently been suggested that in green seedlings blue-light control of hypocotyl extension is due solely to absorption by phytochrome⁴. This claim, together with the evidence that changes in phytochrome photoequilibria can exert profound effects upon stem extension, may lead one to believe that this is the major photoreceptor controlling elongation growth in green plants. We report here, however, work that strongly indicates that two separate pigment systems control hypocotyl extension in green seedlings—phytochrome and a separate blue-light

receptor. Both systems produce the same response—inhibition—but we have found it possible to separate their effects by examining the times at which the response commences.

We have examined in detail the kinetics of the growth responses to light in seedlings of *Cucumis sativus* L which, 3.75 days after germination and growth in darkness (when hypocotyls were 30–40 mm long), were de-etiolated by exposure to white, fluorescent light ('daylight') for 8 h, followed by a 16-h dark period, that is, one 'short-day' pretreatment. At the end of the dark period plants were subjected to the experimental treatments. All plants were grown, and all experiments performed at 25°C. This de-etiolation treatment completely opens the hypocotyl hook, and causes greening and enlargement of the cotyledons. The seedlings are not morphologically identical to, say, the seedlings de-etiolated by 30 h of white light as used by Black and Shuttleworth¹, but they do have the same physiological characteristics as these, that is, phytochrome control of hypocotyl extension by the cotyledons, and loss of the far-red component of the high irradiance reaction¹. Responses with identical timings to those reported below have been obtained with seedlings de-etiolated for 30 h with white light. Returning such seedlings to darkness for several hours gives the same high growth rates as shown by the presently-used material. High growth rates are required for a detailed study of growth kinetics, especially the onset of photoinhibition. Hypocotyl extension in response to light and darkness was monitored using a linear-displacement transducer (ND2, Sangamo Weston Controls Ltd.) in which the counterbalanced, moveable armature was placed at the apex of the plant, between the two cotyledons. After a period of equilibration, extension was recorded continuously and transformed to growth rates (mm h⁻¹) computed at intervals over the growth period. (The few points before 'light on' in Fig. 1*b* illustrate the pre-equilibration rise in growth rate.) A good deal of variability in growth rates is encountered in measurements by transducers. We have found that although the absolute growth rate may vary considerably the timing of the photoresponses is remarkably constant (Table 1). The initial high growth rates of our seedlings allowed us to determine this timing with great definition. Results obtained with conventional measuring techniques are fully consistent with the data reported here which are concerned with the 'ultrastructure' of growth, as it were, obtainable only by means of a highly sensitive device such as a transducer.

Kinetics of light-induced inhibition and of the subsequent recovery in darkness clearly depend upon the spectral region (Fig. 1). The growth rate rapidly falls after about 5 min exposure to blue light, and inhibition reaches a maximum (that is a minimum growth rate) some 35 min later (Fig. 1*a*). On the other hand, red light-induced inhibition starts only 5–6 h after exposure to red light (Fig. 1*b*) and reaches a maximum at 10 h. That this is phytochrome-controlled inhibition is shown by the effectiveness of short periods of red light (10 min every hour), each period being far-red reversible. Thus, to produce photoinhibition several 'inputs' of P_E are required. In practice this is most easily achieved by continuous exposure to red light. The effects of continuous and intermittent red light are, however,

Table 1 Timing of photoresponses controlling hypocotyl extension

Treatment	Time to initial response (mean $\pm$ s.e.m.)	
	Inhibition	Recovery
White fluorescent light	4.25 $\pm$ 0.29 min ($n = 28$)	Short:
		18.9 $\pm$ 1.8 min ($n = 9$)
Red light	5.8 $\pm$ 0.31 h ($n = 21$)	Long:
		10.45 $\pm$ 0.49 h ($n = 19$)
Blue light	5.0 $\pm$ 0.55 min ($n = 9$)	10.0 $\pm$ 0.5 h ($n = 13$)
		18.9 $\pm$ 3.8 min ($n = 9$)

'Short' indicates those white light treatments where the irradiation was given for less than the time for the appearance of phytochrome-controlled inhibition (that is, <3 h). 'Long' refers to those light periods during which phytochrome-controlled inhibition sets in (that is, >8 h).

very close. Moreover, the input of P_{fr} over periods of 1 h and longer produce inhibition, always commencing about 6 h after the beginning of irradiation. We stress that blue light acts directly on the hypocotyl as already reported^{1,6,7}. We observe the same inhibition kinetics in both blue and white light (see below) whether or not the cotyledons are covered. In red light also, covering the cotyledons does not alter the time of onset of inhibition but the 'depth' of inhibition and the timing of recovery are both affected. These latter effects reflect the contribution to photoinhibition made by the cotyledons^{1,6}; the onset of inhibition is presumably due to the action of red light directly upon the hypocotyl^{1,6,7}.

At some time after the end of illumination plants begin to recover from photoinhibition and show a gradually increasing growth rate until a maximum 'dark' rate is obtained. The kinetics of these changes again depend on the spectral region used for previous illumination (Fig. 1a, b). In this and most experiments, recovery from blue light starts slowly, as soon as 5 min after the end of irradiation, with the major increase between 15 and 20 min of darkness, and is complete soon after; but in some experiments the start of recovery was delayed for up to 15–20 min. Red-light inhibition, induced through phytochrome, is much more persistent; about 8 h of darkness are required before the growth rate begins to recover. Thus, blue light inhibits virtually only during irradiation whereas phytochrome-mediated, red-light inhibition has a delayed onset and recovery. Such widely disparate kinetics are difficult to explain on the basis of one pigment system and we conclude, therefore, that hypocotyl extension in de-etiolated *Cucumis* is controlled by two photoreceptors, one being phytochrome and the other an as yet incompletely identified system, specific to blue light^{8,9}. That blue light does not operate through phytochrome in our experimental conditions is further substantiated by the inability of background far-red to alter either the extent or the timing of blue-light inhibition, even though $\phi(P_{fr}:P_{total})$ is reduced from 0.44 to 0.14 (Table 2). There is clearly no correlation between ϕ and the kinetics of photoinhibition.

What of the action of white light? White fluorescent light contains both blue and red wavebands and it therefore activates the specific blue light-sensitive system as well as phytochrome. Onset of inhibition is accordingly rapid (due to blue light) and recovery in darkness after exposure to several hours of white light is slow to develop, presumably because of the long-lasting inhibition caused by phytochrome. It is possible, however, by adjusting the length of the white-light period, to separate the timings of both sets of inhibition and recovery in a single experiment (Fig. 2). Periods of relatively short duration, for example 2–3 h as used in this experiment, produce the rapid inhibition typical of blue light. The characteristic phytochrome-controlled inhibition (red light) does not commence during the

Fig. 2 Effect of a brief white light irradiation. The white light source consisted of 20-W 'daylight' tubes. (Fluence rate as in Table 2.) Crosses mark the mean growth rates calculated every 4 h (shown by the horizontal bar) of similarly treated seedlings, measured by ruler ($n = 12$). As in Fig. 1b these indicate that the seedlings merely recover their growth rate, showing no entrained rhythm.

Table 2 Effect of $P_{fr}:P_{total}$ on the kinetics of photoinhibition

Light source	Fluence rate	$\phi(P_{fr}:P_{total})^*$	Approximate time to start of inhibition (min)
White fluorescent	34 W m ⁻²	0.75	5
Red	8 W m ⁻²	0.75	300
Blue	24 W m ⁻²	0.44	5
Blue + far-red	24 + 6.5 W m ⁻²	0.14	5

*Measured in 15-mm long hypocotyl sections (including hooks) of 3.5-d-old dark-grown seedlings of *Cucumis scitovus* L. using a Perkin Elmer model 156 double wavelength spectrophotometer.

time that the plants are actually exposed to white light, as it requires 5 h for its development to begin (Fig. 1b). Twenty minutes after return to darkness a recovery of growth rate is apparent but ~2 h later this is followed by a second, transient inhibition which occurs in darkness. This comparatively short exposure to white light therefore produces dual kinetics and, we suggest, succeeds in revealing the temporal separation of blue light and phytochrome actions.

The two components of inhibition seem difficult to accommodate in a hypothesis which assigns a role to one pigment only—phytochrome—and appear to us to be best explained as the operation of two separate photosystems, each having different kinetics, in the following manner. The rapid inhibition is due to the blue light effect from which seedlings begin to recover at the end of the light period. The red component of white fluorescent light produces high levels of P_{fr} whose inhibitory action, beginning 5 h after the start of illumination, makes its appearance about 3 h after the plant has returned to darkness. The final recovery of growth rate is the delayed release from phytochrome-induced inhibition. In longer white light periods the actions of the two photosystems become superimposed. Inhibition quickly sets in but the rapid recovery from blue light is obliterated by the long-lasting, red light-induced inhibition, and the observed recovery upon return to darkness thus has only the kinetics which follow phytochrome photoinhibition.

The amount of inhibition caused by blue light depends strongly upon the irradiance, though the timing of the start of inhibition does not. Here we have used high irradiances (fluence rates) to produce substantial and clearly recognisable reductions in growth rate. Pronounced irradiance dependency with regard to the magnitude of inhibition is not found in the case of red light and saturation is achieved by relatively low fluence rates (about 1 W m⁻²). It therefore seems likely that in nature the dependency of hypocotyl and stem extension upon the fluence rate of white light is a response to the blue component. We further suggest that the blue-light system detects fluence rate differences while phytochrome is concerned more with light quality, particularly red/far-red ratios, a point which has been raised by other workers¹⁰. Morgan and Smith¹¹ reported rapid effects of white light on stem extension in de-etiolated *Chenopodium*. The similarity of some of their kinetics to those reported here suggest that the responses of *Chenopodium* to irradiance changes may be attributable to the blue light receptor.

Finally, we should add that the kinetics discussed above account for various growth patterns shown by seedlings held under different daily light regimes. Details of these will be reported elsewhere.

We thank Dr B Frankland and Andrew MacLellan for assistance with phytochrome measurements. V.G. is the holder of an SRC CASE studentship supported by Tate and Lyle.

In vitro duplication of the primary light-induced charge separation in purple photosynthetic bacteria

THE primary light-induced electron transfer events of both green plant and bacterial photosynthesis result in very rapid charge separation which subsequently generates a chemical potential within the organism. There is much information concerning the primary events of bacterial photosynthesis but for green plants the details of these processes are just beginning to become available. Strong evidence based mainly on electron spin resonance and electron-nuclear double resonance studies of oxidised bacterial reaction centres favours a dimeric bacteriochlorophyll *a* (BChl *a*) structure for the primary photochemical electron donor¹. The dimeric BChl *a* species absorbs light at 865 nm in reaction centres from *Rhodospseudomonas sphaeroides* yielding an excited state which rapidly transfers an electron to a molecule of bacteriopheophytin *a* (BPh *a*) in <10 ps (refs 2-4). Within about 150 ps the electron is transferred to a quinone molecule which in turn transfers an electron to a secondary quinone within a few microseconds^{5,6}. In reaction centres for which the quinones have been either extracted or

Fig. 1 PChl *a* dimer in its folded C_2 symmetric conformation.

chemically reduced before light excitation, BPh⁻ back transfers an electron to (BChl *a*)₂⁺ in 10-20 ns (ref. 7). Thus, the *in vivo* geometry of the reaction centre is such that the reverse electron transfer is $5-10 \times 10^3$ times slower than the forward reaction. We now report the first *in vitro* model that duplicates both the rapid light-induced charge transfer and the slow back reaction of the reaction centre.

Covalently linked dimers of BChl *a*, chlorophyll *a* (Chl *a*) and pyrochlorophyll *a* (PChl *a*) have been prepared which mimic the spectroscopic and redox properties of reaction centre chlorophylls⁸⁻¹⁰. The two chlorophylls are joined in each case at their propionic acid side chains through an ethylene glycol diester

linkage. The orientation of the chlorophyll macrocycles with respect to one another, and consequently their electronic properties, are highly solvent dependent. Treating solutions of these covalent dimers in dry non-nucleophilic solvents (such as benzene, toluene, CCl_4) with 10-100-fold molar excesses of a hydrogen-bonding nucleophile (such as water, primary alcohols, primary thiols) results in their folding into the C_2 symmetric conformation shown in Fig. 1. This structural assignment is based primarily on ¹H NMR spectral evidence^{8,10}. The folding is accompanied by shifts of both the longest wavelength absorption in their electronic transition spectra and their fluorescence maxima to longer wavelengths.

Fig. 3 *a*, Fluorescence spectrum of 0.2 mM PChl *a* dimer in toluene containing 20 mM ethanol. Excitation at 530 nm. *b*, Fluorescence spectrum of 0.2 mM PChl *a* dimer in toluene containing 0.8 mM PPhide *a*-OH. Excitation at 530 nm.

We used the PChl *a* dimer to produce a functional model reaction centre because of its inherent stability towards photo-degradation¹¹. The PChl *a* dimer was prepared by a method described elsewhere⁸. Folding this dimer into the conformation shown in Fig. 1 results in a shift of its absorption maximum from 663 nm to 694 nm, whereas its fluorescence maximum shifts from 670 nm to 735 nm. To position pheophytin *a*, which serves as the electron acceptor, close to the dimer, we have used the strategy of replacing the hydrogen-bonded short-chain alcohol which secures the conformation of the dimer shown in Fig. 1 with a primary alcohol derivative of pheophytin *a*. The pyropheophorbide *a* ethylene glycol monoester (PPhide *a*-OH), a precursor of the PChl *a* dimer, proves to be ideal for this.

When dry 0.2 mM solutions of PChl *a* dimer in toluene are treated with as little as a fourfold molar excess of PPhide *a*-OH at room temperature or a stoichiometric twofold molar excess at

Fig. 2 Proposed structure of the (PChl *a*)₂-(PPhide *a*-OH)₂ reaction centre model.

0°C, the dimer readily folds into the structure shown in Fig. 2 (^1H and ^{13}C NMR structural evidence, M.R.W., unpublished). This folding is accompanied by a shift of the dimer electronic absorption maximum to 694 nm. More importantly, the 735 nm fluorescence of the dimer is almost completely quenched (Fig. 3). If a similar experiment at the same concentrations is carried out with PChl *a* dimer folded with ethanol while unbound pheophytin *a* is present in the solution, the fluorescence quantum yield of the dimer actually increases by about 10% over that seen in the absence of pheophytin *a*. This effect may be attributed to excitation energy transfer from excess pheophytin *a* in solution to the folded dimer which acts as an energy trap.

To determine the mechanism and kinetics of the quenching of the PChl *a* dimer fluorescence by PPhide *a*-OH in our model reaction centre, we have determined the excited state difference spectrum of the model as a function of time on the picosecond time scale. The experimental apparatus and techniques used to obtain the data have been described elsewhere¹². Fig. 4 shows the difference in optical density between the excited state and the ground state following a 6-ps flash at 530 nm.

The rise time for all ΔA changes is <6 ps. These changes persist for 10–20 ns with the subsequent return of the ground state absorption spectrum. The spectrum in Fig. 4 displays a positive ΔA change at 800 nm and strong bleaching at 660 nm.

Fig. 4 Initial absorption changes following 6 ps excitation with 530 nm light of 0.2 mM PChl *a* dimer and 0.8 mM PPhide *a*-OH in toluene at 20°C.

Positive ΔA changes dominate the 440–630-nm region of the spectrum. The 800-nm feature in the spectrum is characteristic of a Chl *a* cation radical¹³. The one electron oxidation product of the PChl *a* dimer folded with ethanol displays a broad electronic absorption near 800 nm. Similarly, P_{700} in green plants undergoes light-induced oxidation to yield a species which absorbs light near 800 nm (ref. 14). The strong bleaching at 660 nm and the smaller bleachings at 500 nm and at 530 nm can be ascribed to the disappearance of ground state PPhide *a*-OH. One electron reduction of pheophytin *a* results in very similar spectral changes¹⁵. Thus, the overall spectrum in Fig. 4 may be adequately described as a superposition of the PChl *a* dimer cation radical spectrum and the PPhide *a*-OH anion radical spectrum. Whether the complex exists as a radical pair or as a charge transfer state has not yet been ascertained. The overall spectral features strongly parallel the type of spectral changes observed following flash excitation of bacterial reaction centres even though the wavelengths of the ΔA changes are different for the *a*-series plant chlorophylls^{2–4}. Based on the fluorescence quenching data and assuming reasonable values for the oscillator strength of the 800-nm transition in (PChl *a*)₂⁺, the quantum efficiency of electron transfer in our model approaches

unity. Thus, our model reaction centre channels most of the light energy it absorbs into an electron transfer process which displays the same asymmetric kinetics as observed *in vivo*.

It is clear from our experiments that positioning the PPhide *a*-OH electron acceptor close to the PChl *a* dimer electron donor is important for efficient light-induced electron transfer. However, the kinetics of both the forward and reverse transfers depend critically on the energies of the states involved. Excitation of the PChl *a* dimer into its first excited singlet state raises its energy to ~1.8 eV above the ground state. Charge separation is then an energetically 'downhill' process with the resultant ion pair state ~1.5 eV above the ground state (estimated from the difference between the one electron oxidation potential of the folded PChl *a* dimer, 0.50 V compared with SCE, and the one electron reduction potential of PPhide *a*-OH, -1.02 V compared with SCE, in methylene chloride). The ~0.3-eV energy difference between the singlet and ion pair states is sufficient for a rapid forward transfer rate, but results in the reverse electron transfer being an activated process. Thus, the rate of an electron transfer leading back to the first excited singlet state should be substantially slower than the charge separation rate.

The only reasonable pathway remaining for the ion pair state is to cross over to a highly vibrationally excited state of the ground electronic state. As $\Delta G \ll 0$, ~-1.5 eV, the Franck-Condon factors for this process are small and thus the rate of return to the ground state is relatively slow.

Because the PPhide *a*-OH molecules may exhibit some conformational freedom due to rotation about the single bonds of their alkyl chains, the role of these changes following excitation and their effect on the reverse electron transfer rate need to be further explored. In conclusion, we have successfully modelled the primary light-induced charge separation chemistry in reaction centres of purple photosynthetic bacteria by using *in vitro* reaction centre models based on chlorophyll derivatives.

Antigen specific T-cell helper factor cross reacts idiotypically with antibodies of the same specificity

THE recognition system of bone marrow-derived (B) cells and their products is based on the interaction of the active site of immunoglobulins with the specific antigenic determinants. However, the molecular nature of the recognition component of thymus-derived (T) lymphocytes is not yet established. Studies on antigen specific T-cell helper or suppressor factors¹⁻⁵ and isolation of the antigen receptor directly from T cells, or from serum^{6,7} are examples of approaches to elucidate this problem. The synthetic polypeptide poly(Tyr,Glu)-poly(DLAla)-poly(Lys) [abbreviated (T,G)-A--L] has been extensively used in studies on the molecular basis of antigenicity⁸ and genetic regulation of immune responsiveness⁹⁻¹¹. Studies on the antibody response to (T, G)-A--L have revealed the involvement of several cell types and a T-cell replacing soluble factor which are antigen specific and genetically controlled¹²⁻¹⁴. An important feature of the T-cell factors is their antigen specificity. The specificity of a T-cell factor produced to (T, G)-A--L was demonstrated by the removal of its activity on specific antigen-Sepharose columns¹⁵ and also by demonstrating that the *in vivo* helper effect was specific to the antigen used in the T cell education^{1,16}. It is very likely that the specific T-cell factor represents the molecular recognition component of T cells—the T-cell receptor. If this is the case, the molecular identification and characterisation of the T-cell factor may answer one of the most controversial questions in immunology. It has been suggested that antigen-specific molecules of B and T cells share idiotypic determinants^{17,18}. It was, therefore, of interest to find out whether the (T, G)-A--L specific factor will share idiotypic determinants with antibodies of the same specificity. The results of the present study demonstrate that B-cell products (antibodies) and T-cell products (factors) possess cross-reacting idiotypic determinants. This strongly suggests the presence of similar variable regions in both antigen binding entities, which are probably coded by the same variable region genes. Cross-reactive idiotypic determinants are also present on (T, G)-A--L specific factors obtained from low responder C3H/DiSn T cells confirming previous reports on the activity of these factors.

The successful production of anti-idiotypic antisera in guinea pigs to C3H.SW anti-(T, G)-A--L antibodies has been recently reported¹⁹. Idiotypic determinants recognised by these sera were present in anti-(T, G)-A--L antibodies from different individuals of C3H.SW mice. A linkage between the expression of the cross-reactive idiotypes and heavy chain constant region allotypes was demonstrated¹⁹. This characterised anti-idiotypic serum was used in the present study to look for the presence of idiotypic determinants on the (T, G)-A--L specific T-cell factor. Indeed, the activity of a (T, G)-A--L specific factor was removed after passage through an immunoadsorbent of Sepharose-coupled anti-idiotypic serum.

The (T, G)-A--L specific T-cell factors were produced by 'educated' T cells of C3H.SW, CWB and C3H/DiSn inbred mouse strains as described elsewhere²⁰. The helper activity of the factors was assayed by transferring them into irradiated mice together with high responder (C3H.SW) bone marrow cells and (T, G)-A--L²⁰. The immune response was followed by determining the anti-(T, G)-A--L haemagglutination titres in the sera of the recipients²⁰. The anti-idiotypic serum prepared in guinea pigs against C3H.SW anti-(T, G)-A--L antibodies was the same as previously reported¹⁹. The IgG fraction (10 mg) of the anti-idiotypic serum was coupled to 1 g of Sepharose²¹.

As shown in Table 1, a factor produced by C3H.SW (high responder) educated T cells replaced the helper function of thymocytes in eliciting an antibody response to (T, G)-A--L. The activity of this factor was completely removed by passage through the anti-idiotypic-Sepharose immunoadsorbent,

whereas no effect on the activity of the factor was observed when normal guinea pig IgG or guinea pig anti-mouse IgG were used as immunoadsorbents.

C3H/DiSn (H-2^b) low responder mice are capable of producing a (T, G)-A--L specific factor which cooperates with high responder (H-2^b) B cells for the production of antibodies (see Table 1 and ref. 20). The factor produced by C3H/DiSn mice was removed by the anti-idiotypic antibodies. As with the (T, G)-A--L specific factor from C3H.SW mice, the activity of the factor from C3H/DiSn mice was completely retained after passage through guinea pig anti-mouse IgG immunoadsorbent.

Table 1 Effect of anti-idiotypic antibodies on the helper activity of (T, G)-A--L specific T-cell factors

C3H.SW bone marrow cells and (T, G)-A--L transferred with:	No. of animals	No. of experiments	log ₂ haemagglutination titres
No addition	31	4	0.77 ± 0.2
10 ⁸ C3H.SW thymocytes	19	4	4.21 ± 0.6
C3H.SW factor	30	4	4.37 ± 0.03
C3H.SW factor passed on an anti-idiotypic-Sepharose column	30	4	1.03 ± 0.21
C3H.SW factor passed on a normal guinea pig-Sepharose column	19	3	4.74 ± 0.35
C3H.SW factor passed on a guinea pig anti-mouse IgG-Sepharose column	6	1	3.7 ± 0.34
C3H/DiSn factor	11	2	4.0 ± 0.22
C3H/DiSn factor passed on an anti-idiotypic-Sepharose column	11	2	1.09 ± 0.39
C3H/DiSn factor passed on a guinea pig anti-mouse IgG-Sepharose column	12	2	3.75 ± 0.18
CWB factor	6	1	4.0 ± 0.36
CWB factor passed on an anti-idiotypic-Sepharose column	4	1	4.0 ± 0

C3H.SW recipient mice were irradiated (850 R) and reconstituted with 2×10^7 syngeneic bone marrow cells, 10 µg of (T, G)-A--L and either thymocytes or (T, G)-A--L specific T-cell factors produced by one spleen equivalent of educated T cells. Mice were bled 12 d after transfer and their sera assayed by passive haemagglutination with (T, G)-A--L coated sheep red blood cells. Values are means ± s.e.m.

CWB (H-2^b, Ig-1^b) mice are high responders to (T, G)-A--L. They are congenic with C3H.SW (H-2^b, Ig-1^a) mice and differ only in their heavy chain allotypic markers. Anti-(T, G)-A--L antibodies of CWB mice do not share idiotypic determinants with antibodies of C3H.SW mice¹⁹. It was, therefore, of interest to find out whether a factor of CWB mice would react with the anti-idiotypic antibodies. As demonstrated in Table 1, the CWB factor was not affected by the anti-idiotypic antibodies against C3H.SW anti-(T, G)-A--L.

As shown for antibodies, the ability to produce a (T, G)-A--L specific factor which cross reacts with C3H.SW anti-(T, G)-A--L antibodies is linked to the Ig-1 allele of the mouse strain.

Note that the anti-idiotypic serum bound only 30% of the idiotypes (C3H.SW anti-(T, G)-A--L antibodies)¹⁹ whereas in this study we have demonstrated that the activity of the factor was completely removed by the anti-idiotypic immunoadsorbent. As the activity of the factor is lost on dilution (at fourfold or higher dilutions, data not shown) it is possible that most but not all of the factor present was removed by the anti-idiotypic. It is, of course, possible that the particular type of the gene product

that is expressed in the anti-(T, G)-A-L antibodies to the extent of 30% and bears the cross-reactive idiotype determinants, is expressed to a higher extent in the population of the factor molecules of the same specificity. This, however, does not exclude the possibility that T- and B-cell products have potentially the same repertoire but that regulation processes determine a different expression of a particular type in one or the other type of recognition entities. Indeed, it is clear that antibodies of different classes with the same specificity share the same V region repertoire but that antibodies of the IgG class reach a higher affinity upon maturation than those of the IgM class²². It has also been shown recently in another system that the T-cell receptor is restricted to only part of the idiotypes expressed by antibodies²³.

In contrast to our findings in mice, it has been reported that an antigen-specific T-cell factor produced in rabbits did not show the presence of V_H markers²⁴, namely a locus allotype, whereas a receptor directly isolated from rabbit T cells did show the presence of V_H-related allotypic determinants²⁵.

It is noteworthy that the antigen-specific T-cell helper factors have been shown to possess Ia determinants^{1,2,26}. Thus, these factors are coded by two unlinked genes. A similar conclusion has been drawn from genetic studies with an anti-idiotypic serum to a T-cell receptor²⁷. The molecular basis of the combination between I region gene products and immunoglobulin variable region gene products is not yet understood. Preliminary experiments in our laboratory suggest that the two determinants are part of one entity since combination of effluents passed separately on anti-Ia and anti-idiotypic immunoadsorbents did not result in an active helper factor.

Is synaptic facilitation caused by presynaptic spike broadening?

FACILITATION is a characteristic of many synapses whereby the efficacy of synaptic transmission increases following presynaptic activity. This form of neuronal plasticity has been implicated in behavioural modifications such as habituation¹ and learning². Facilitation has been shown to be due to a presynaptic increase in transmitter release³, but its biophysical mechanism remains obscure. Although it is often suggested that facilitation is due to the action of a residual increase in intracellular free calcium⁴, an alternative hypothesis, that facilitation may be caused by action potential prolongation, has recently been proposed⁵⁻⁷. In molluscan neural somata, spike broadening occurs in a train of impulses, due to non-inactivating calcium channels and cumulatively inactivating potassium channels⁷. This might result in an increased calcium influx associated with prolonged spikes⁸, which would lead immediately to facilitated transmitter release⁹. We show here that at crustacean neuromuscular junctions, spike broadening is not primarily responsible for facilitation.

In previous work on neuromuscular junctions, no presynaptic spike broadening was observed, and facilitation could be evoked by repeated terminal depolarisation^{10,11}. However, the extracellular recording method used is particularly insensitive to changes in spike duration¹², and a cumulative potassium inactivation would invalidate the interpretation¹³ of the effect of extracellular stimulation on presynaptic nerve polarisation. Moreover, the effect of caesium on neuromuscular transmission is consistent with the spike broadening facilitation hypothesis. Caesium prolongs nerve terminal potentials (n.t.ps) (probably by blocking potassium channels), increases the number of quanta released by an impulse, and reduces facilitation at crab neuromuscular junctions^{14,15}. Similarly, in molluscan somata, when the inactivating outward current is blocked pharmacologically, the spikes are all broadened, but progressive spike prolongation in a train is prevented.

An alternative explanation for the caesium effect¹⁰ is that the longer n.t.ps may simply be releasing all the transmitter immediately available for release, so that the transmitter release is saturated. Then, whatever processes are responsible for facilitation may still be operable in caesium, but are not expressed, as facilitation of the already saturated release of transmitter is impossible.

These alternatives may be distinguished by soaking neuromuscular junctions in a caesium-substituted potassium-free saline, and then reducing calcium and raising magnesium

Fig. 1 Extracellular recordings of nerve potentials and synaptic currents from synaptic sites. a-c Are from three separate preparations and show responses at 1 and 10 Hz in normal saline (a), 5.4 mM potassium replaced by caesium with normal calcium and magnesium (b), and 5.4 mM caesium with 1 mM calcium and 15 mM magnesium (c). d, Responses from a single preparation stimulated at 10 Hz are shown in the three experimental solutions. All traces are computer-averaged responses to 64 stimuli. Calibration bars 0.1 mV, 2 ms

Table 1 Effects of caesium or 4-aminopyridine in normal and low-calcium media on synaptic transmission and facilitation

'Control', normal saline (as in ref. 3, except that 10 mM HEPES buffer is used to hold pH to 7.3), 'Ca', 5.4 mM caesium substituted for potassium, 'AP', saline plus 25 μ M 4-aminopyridine; 'Ca low-Ca', 5.4 mM caesium substituted for potassium, calcium reduced from normal (13.5 mM) to 1 mM, and magnesium raised from normal (2.5 mM) to 15 mM, 'AP low-Ca', saline with 25 μ M 4-aminopyridine, 1 mM calcium and 15 mM magnesium. In the last two solutions, the calcium and magnesium concentrations were buffered with EDTA¹⁶ and the calculated calcium concentration was confirmed with an Orion ion-selective electrode. Excitatory junctional potential (e.j.p.) amplitudes were corrected for the nonlinear relation between transmitter release and e.j.p. amplitude, using Martin's revised correction procedure²², which is applicable to crustacean muscles because their multi-terminal innervation and short electrotonic length make them nearly isopotential²³. The membrane time constant was estimated from the e.j.p. falling phase and the synaptic current time course was derived from the e.j.p. time course²⁴ or measured from the extracellularly recorded synaptic current. Caesium and low calcium had little effect on the synaptic current time course, so errors in estimating transmitter release due to changes in release synchrony were averted^{25,26}. Each e.j.p. amplitude given is the average of at least 10 measurements. The standard errors were lower than 11% in each case (typically 5%) and are not shown. Facilitation is expressed as the fractional increase in transmission at 10 Hz compared with that at 1 Hz. A facilitation index of unity signifies a doubling in transmitter release.

until transmitter release is restored to near the control level in normal saline. As either calcium reduction or blockade of potassium currents prevents spike broadening in molluscan somata, both treatments combined ought to be doubly effective in preventing facilitation due to spike broadening. In contrast, if spike broadening does not normally occur at crustacean nerve terminals and has nothing to do with facilitation, reducing calcium and elevating magnesium should return transmitter release to a non-saturated level and facilitation should reappear. It was shown previously¹⁶ that changes in calcium concentration alone do not affect facilitation.

Table 1 shows the results of six experiments in which we recorded intracellularly from crayfish (*Procambarus clarkii*) claw opener muscles while stimulating the opener motor neurone, using procedures described elsewhere^{3,10}. Replacing potassium with caesium increased transmission 3–100-fold. Facilitation was reduced to 18–61% of its control value. On

reducing the free calcium and increasing the free magnesium concentration, transmission is reduced and facilitation restored, the degree of restoration of facilitation corresponding roughly to the extent to which transmission is restored to the control level.

Caesium and low-calcium-high-magnesium might have unexpected effects on spike duration that would argue against our interpretation of their effects on facilitation. From previous observations of n.t.ps at different frequencies³, we would expect the presynaptic action potential duration to be unchanged at 10 Hz relative to 1 Hz in each of the experimental solutions. Figure 1a–c confirms this prediction. Moreover, we would expect the n.t.p. to be prolonged in the presence of caesium and that this effect would not be reversed by reducing the calcium-to-magnesium concentration ratio. This expectation was also confirmed (Fig. 1d).

To generalise our results, we chose to determine whether similar effects would be obtained using a different pharmacological agent, 4-aminopyridine (4-AP), for blocking potassium channels¹⁷. To obtain effects quantitatively comparable with those of 5.4 mM caesium, we treated neuromuscular junctions with 25 μ M 4-AP (the half-maximal dose of 4-AP is about 50 μ M). We found that, as with caesium, facilitation was markedly reduced and that this effect was largely reversed by reducing the calcium concentration. The results of six experiments are included in Table 1.

In squid axon, both caesium and 4-AP block voltage-dependent potassium channels^{17,18}. In molluscan somata, caesium blocks voltage-dependent channels, whereas 4-AP has little effect on delayed potassium activation^{19,20}. Neither agent seems to block calcium-activated potassium channels. It seems probable that both agents are blocking a voltage-dependent potassium current in crayfish nerve terminals. As these voltage-dependent channels are thought to be the ones subject to progressive inactivation in dorid nudibranchs⁷, blocking them should prevent spike broadening, especially in low calcium, because a persistent calcium current is also required for the expression of progressive spike broadening⁷. The large facilitation we observe in the presence of either 4-AP or caesium and reduced calcium argues against the notion that spike broadening due to potassium inactivation is responsible for synaptic facilitation. Rather, the block of facilitation by caesium and 4-AP in normal calcium seems to be due to a saturation of transmitter release.

There is also some evidence that in snails the calcium-activated potassium channels are subject to inactivation, contributing to spike broadening⁶. Such channels should not be activated in low calcium^{6,21}. The persistence of facilitation in 1 mM calcium in these experiments and even in 10 and 100 μ M calcium (ref. 16 and R.S.Z., unpublished) argue against the notion that spike broadening due to inactivation of calcium-activated potassium channels could underlie facilitation. Thus, it seems that facilitation at crayfish neuromuscular junctions arises in some step of depolarisation-secretion coupling following the generation of the presynaptic electrical signal.

Striatal dopamine receptors become supersensitive while rats are given trifluoperazine for six months

OF all the side effects of drugs used to treat psychotic illness such as schizophrenia, chronic tardive dyskinesias are the most disturbing. They appear after months or years of therapy, and persist when the offending drug is withdrawn in about half of the cases. Such tardive dyskinesias resemble in character abnormal movements produced by levodopa in patients with Parkinson's disease. They can be controlled by drugs that antagonise the cerebral actions of dopamine (DA)¹. Thus, they seem to be due to overstimulation of cerebral DA receptors, although they are caused by neuroleptic drugs which, in acute experiments, antagonise cerebral dopamine receptor action^{2–5}. This paradox has been resolved by suggesting that such drugs, by binding to and antagonising cerebral DA receptors, may eventually actually increase receptor sensitivity. Indeed, following treatment for a few weeks with phenothiazines or butyrophenones and withdrawal of the drugs, animals exhibit behavioural and biochemical supersensitivity to DA agonists which persists for some time^{6–13}. However, tardive dyskinesias usually appear while the patient continues to take the offending drug, so we have studied the effect on striatal DA receptor activity of continuous 6-month administration to rats of a potent neuroleptic drug in common clinical use (trifluoperazine). At intervals the animals were tested for a behavioural response to the DA agonist apomorphine, and were killed for biochemical assessment of DA turnover and DA receptor activity in that part of the brain (the corpus striatum) believed to be the site responsible for production of tardive dyskinesias. We report here that the initial behavioural and biochemical evidence for striatal DA receptor blockade by trifluoperazine disappears within a few weeks of starting therapy, to be replaced by supersensitivity after 6 months of drug administration, despite continued drug intake.

Trifluoperazine hydrochloride (Smith, Kline and French, 2.5–3.5 mg per kg per day) was administered in the drinking water for 6 months to male Wistar rats (Olac International; weight 200 g at the start of the experiment). The drug was made up freshly in distilled water (with ascorbic acid added) each day in darkened bottles. Control animals were given distilled water alone. All animals were kept in the same environment at 21 ± 3 °C on a regular 12-h night/day cycle. At intervals (usually after 1 and 2 weeks, and 1, 3 and 6 months) trifluoperazine-treated and control rats were assessed as follows: spontaneous locomotor activity, presence of catalepsy, and incidence and severity of stereotypy induced by apomorphine hydrochloride (Evans Medical; 0.5 mg per kg, subcutaneously (s.c.), given 15 min previously). At the same intervals, groups of trifluoperazine-treated and control rats were killed by decapitation and the paired corpus striatum was rapidly dissected out for: (1) fluorimetric assay of DA and its major metabolites homovanillic acid

(HVA) and 3,4-dihydroxyphenylacetic acid (DOPAC) according to the techniques of Westerink and Korf¹⁴; (2) assay of basal and dopamine (1–150 μM) stimulated adenylate cyclase according to the technique of Miller, Hearn and Iverson¹⁵ (ED₅₀ values for dopamine stimulation varied between runs due to inherent changes in assay procedure. This problem was overcome by running control samples and samples from drug-treated animals in strict parallel throughout the entire procedure. Attention should be paid to changes in relative ED₅₀ values); (3) specific ³H-spiroperone (20 Ci mmol⁻¹; Radiochemical Centre) binding using a range of 0.125–4.0 nM radioactive ligand and DA (10⁻⁴ M) to define specific binding as modified from the technique of Creese, Burt and Snyder¹⁶ (³H-spiroperone binding in striatum is to DA receptors¹⁷). The results are summarised in Tables 1 and 2.

After an initial period of weight loss in the first week the animals tolerated trifluoperazine well, gaining weight at the same rate as control animals, and regularly ingesting between 2.5 and 3.5 mg per kg per d. For the first week spontaneous locomotion was reduced in trifluoperazine-treated animals which were moderately cataleptic. Thereafter, these rats regained normal activity and catalepsy disappeared so that they were indistinguishable in these respects from control animals by 3 and 6 months.

Administration of apomorphine (0.5 mg per kg, s.c.) to control animals at each testing period resulted in the production of mild stereotypy consisting of discontinuous locomotion and sniffing. Apomorphine-induced stereotypy was antagonised by trifluoperazine in the first month of treatment, had returned to control levels by 3 months, and was enhanced after 6 months, the animals exhibiting pronounced licking, gnawing or biting (Table 1). From consideration of the proportion of animals continuously exhibiting this behaviour to a range of doses of apomorphine (0.125–2.0 mg per kg, s.c.), the dose-response curve for maximum stereotypy was found to have shifted to the left in the animals treated with trifluoperazine for 6 months, compared with control rats.

Striatal DA concentrations were unaltered, whereas HVA and DOPAC levels were increased in the first weeks of drug administration, but thereafter the increase in DA metabolites in the striatum disappeared rapidly, as has been observed by others^{18,19} (Table 1). Striatal DA, HVA and DOPAC levels after 6 months of trifluoperazine treatment were not consistently different from those in age-matched control rats.

The increase in striatal adenylate cyclase activity from basal levels was linearly related to added DA concentration between 1 and 150 μM in control animals. In the first month of trifluoperazine intake, more DA was required to produce an equivalent stimulation of striatal adenylate cyclase above basal

Table 1 Effect of 6 months of oral administration of trifluoperazine (2.5–3.5 mg per kg per d) on apomorphine-induced stereotypy and striatal DA, HVA and DOPAC levels compared with controls

Time	Apomorphine-induced stereotypy score		% Of control		
	Control group	Drug-treated group	DA	HVA	DOPAC
1–2 weeks	2.0 ± 0.0	0.0 ± 0.0†	98 ± 7	234 ± 31†	238 ± 34†
1 month	2.0 ± 0.0	0.3 ± 0.2†	—	122 ± 15	107 ± 9
3 months	2.3 ± 0.2	1.6 ± 0.2	130 ± 9*	124 ± 5	88 ± 5
6 months	2.1 ± 0.1	3.1 ± 0.1*	89 ± 10	118 ± 7	110 ± 10

Apomorphine-induced (0.5 mg per kg, s.c.) stereotypy was assessed according to the scale: 0 = normal, 1 = continuous locomotor activity, discontinuous sniffing, 2 = discontinuous locomotor activity, continuous sniffing, 3 = discontinuous biting, licking and gnawing, 4 = continuous biting, licking or gnawing. The results are expressed as the mean ± 1 s.e.m. for 6 animals in each group. Striatal DA, HVA and DOPAC levels were measured by the technique of Westerink and Korf¹⁴, in 6 control and 6 drug-treated animals at the time intervals shown. Values for control animals for DA were 11.1 ± 0.9 μg per g, for HVA 93 ± 57 ng per g and for DOPAC 850 ± 63 ng per g (± 1 s.e.m.) and showed no change with age. All data obtained in drug-treated animals were compared with those obtained in age-matched untreated animals kept in otherwise identical conditions and studied at the same time.

* $P < 0.05$, † $P < 0.005$, compared to control animals, Student's *t* test for parametric data; Mann-Whitney *U* test for non-parametric results.

Table 2 Effect of 6 months of oral administration of trifluoperazine (2.5–3.5 mg per kg per d) on dopamine stimulation of striatal adenylate cyclase and specific striatal ^3H -spiperone binding compared with controls

Time	Stimulation of adenylate cyclase caused by 50 μM DA (pmol cAMP per 2 mg tissue per 2.5 min)		Total specific ^3H -spiperone binding (pmol per mg)	
	Control group	Drug-treated group	Control group	Drug-treated group
1–2 weeks	107 $\pm$ 6	41 $\pm$ 19*	11.7 $\pm$ 0.4	11.0 $\pm$ 0.5
1 month	106 $\pm$ 18	51 $\pm$ 27*	11.3 $\pm$ 0.8	4.7 $\pm$ 0.2*
3 months	48 $\pm$ 11	61 $\pm$ 19	—	—
6 months	55 $\pm$ 15	90 $\pm$ 24*	8.1 $\pm$ 0.2	9.8 $\pm$ 0.4*

The DA stimulation of striatal adenylate cyclase caused by 50 μM DA was calculated from the linear portion of the concentration (1–150 μM DA)–response curve, obtained by regression analysis, as determined by incubating striatal tissue from 3 control or drug-treated rats with the range of concentrations (each determination being carried out in duplicate). Total specific ^3H -spiperone binding (as judged by DA 10^{-4} M displacement) was determined at nonsaturating substrate concentration (0.25 and 0.50 nM). Data were obtained by using pooled tissue from at least 6 control or drug-treated animals with each determination being carried out in triplicate. All data obtained in drug-treated animals were compared with those obtained in age-matched untreated animals kept in otherwise identical circumstances and studied at the same time.

* $P < 0.005$ Student's t test.

levels, and the concentration of DA required to produce a 50% increase in adenylate cyclase from basal levels (ED_{50}) was increased to 87 μM , compared with 6 μM in age-matched control animals. After 3 months of trifluoperazine treatment the ED_{50} for added DA was barely different from that required in control animals (66 μM and 72 μM , respectively). However, by 6 months, 50 μM produced a greater percentage increase in adenylate cyclase from basal level compared with control animals and the ED_{50} was less in drug-treated than control animals (4 μM and 32 μM , respectively) (Table 2).

Total specific binding of ^3H -spiperone to striatal membranes was less in trifluoperazine-treated animals compared with controls at nonsaturating ligand concentrations after 1 month of drug intake (Table 2). Scatchard analysis showed this to be due to a reduced receptor affinity in animals treated for 1 month relative to control animals (K_D 1.04 $\pm$ 0.13 nM compared with 0.32 $\pm$ 0.05 nM for controls; $P < 0.005$) whereas total number of binding sites was unchanged (15.1 $\pm$ 1.7 pmol per g compared with 19.3 $\pm$ 2.6 pmol per g for controls). However, by 6 months total specific ^3H -spiperone at ligand concentrations below saturation was greater in trifluoperazine-treated than in age-matched control animals (Table 2). Scatchard analysis revealed a tendency for increased receptor affinity (K_D 0.50 $\pm$ 0.06 nM compared with 0.67 $\pm$ 0.06 nM for control animals; $P < 0.08$) with no obvious change in number of binding sites (23.4 $\pm$ 2.5 pmol per g, and 20.7 $\pm$ 1.7 pmol per g for control animals).

The effect of chronic trifluoperazine administration in increasing receptor affinity was seen more clearly by comparing the dissociation constant after 1 month of drug treatment with that after 6 months (K_D 1.04 $\pm$ 0.13 nM and 0.50 $\pm$ 0.06 at 1 and 6 months, respectively; $P < 0.01$). Thus, the dissociation constant fell between 1 and 6 months of trifluoperazine therapy, indicating an increased receptor affinity. By contrast, in control animals the reverse occurred, namely an increased dissociation constant (K_D 0.32 $\pm$ 0.05 nM and 0.67 $\pm$ 0.06 nM at 1 and 6 months, respectively; $P < 0.007$), indicating a decrease in receptor affinity with normal ageing. Furthermore, comparison of the number of binding sites at 1 and 6 months shows a small increase in trifluoperazine-treated animals (15.1 $\pm$ 1.7 pmol per g to 23.4 $\pm$ 2.5 pmol per g; $P < 0.02$), but no change in control animals (19.3 $\pm$ 2.6 pmol per g, 20.7 $\pm$ 1.7 pmol per g; $P < 0.05$).

Our results indicate a fairly consistent general conclusion, supported by a variety of different behavioural and biochemical

observations. Trifluoperazine administration in the first days or weeks caused antagonism of DA-mediated behaviour, a compensatory increase in striatal DA turnover, decreased capacity for DA stimulation of striatal adenylate cyclase, and decreased striatal ^3H -spiperone binding. All these effects may be attributed to the acute or subacute actions of these drugs in brain tissue. Even the *in vitro* adenylate cyclase and ^3H -spiperone binding changes probably represent the effects of residual drug in the tissues studied.

Over the next 6 months, trifluoperazine intake remained constant and we assume that brain levels of the drug did not change in a manner that might explain our results. A gradual accumulation of the drug might occur, but not a progressive decrease in brain trifluoperazine concentration. In any event, the changes we observed over the months of chronic trifluoperazine intake were not a gradual decline of the acute effects of the drug, but a reversal of these actions.

After 1 to 3 months of trifluoperazine intake, spontaneous locomotor activity, stereotypy induced by apomorphine, striatal dopamine turnover, adenylate cyclase and ^3H -spiperone binding had all returned to normal, as judged by age-matched control rats. After 6 months, drug-treated animals were supersensitive to apomorphine in respect of maximum stereotypy, and showed increased sensitivity for DA stimulation of striatal adenylate cyclase and increased ^3H -spiperone-defined receptor affinity. Thus, a drug which initially caused behavioural and biochemical antagonism of DA effects in the striatum produced the opposite effects after 6 months' administration, namely enhanced striatal dopamine action.

Does this reversal of trifluoperazine's effect on DA action during chronic administration apply to other neuroleptic drugs? So far, we have obtained similar results for thioridazine (30–40 mg per kg per day) showing a reversal of all these behavioural and biochemical indices of DA action over 6 months' intake.

We consider our results to indicate that as far as striatal DA receptors are concerned, the initial antagonistic effects of neuroleptic drugs are replaced by some evidence of supersensitivity despite continued drug intake. This would explain why drug-induced parkinsonism may disappear and why tardive dyskinesias may appear during chronic neuroleptic therapy. Furthermore, this type of experiment may provide a realistic animal model for testing drugs for their capacity to induce tardive dyskinesias.

Finally, it is reasonable to wonder whether changes similar to those observed in the striatum occur in the mesolimbic and mesocortical DA areas of the brain. If so, and the necessary experiments are under way in our laboratories to study this, the whole concept of antipsychotic drugs acting primarily by antagonising cerebral DA receptors may require revision.

We thank Sandoz and Smith, Kline and French for supplies of drugs, the Research Funds of Bethlem Royal and Maudsley Hospitals and the Mental Health Foundation for financial assistance.

Effects of insulin on insulin-binding components extracted from rat fat cell membranes

WE have previously shown the presence of two distinct insulin-binding species (designated species I and II) in a Triton X-100 extract of fat cell membranes¹. They were separable electrophoretically and displayed different insulin-binding characteristics. Scatchard analysis of the insulin-binding data for species I indicated a complex, non-classical association, illustrated by a curvilinear plot. The characteristics of this curve are quite similar to those of the binding curves obtained with unfractionated detergent extract or with intact plasma membranes¹. In contrast to these findings, insulin-binding to species II was characterized by a relatively low affinity and a linear Scatchard plot. Although these findings indicate different insulin-binding and electrophoretic properties for the two species, the possibility remains that they are related structurally. For example, the K_d values for the low-affinity portion of the peak I Scatchard plot and for insulin binding to peak II are similar. Furthermore, following the incubation of isolated peak I with ¹²⁵I-labelled insulin and subsequent electrophoresis, a small amount of radioactivity migrated in the position of peak II (ref. 1). We report here that interconversion occurs between the two binding species and that the conversion is mediated by insulin.

Soluble insulin-binding material was prepared by treating a purified plasma membrane fraction from rat adipocytes with 1% (v/v) Triton X-100 as described by Cuatrecasas². Particulate material was removed by centrifugation of the detergent suspension at 150,000g for 90 min at 4 °C. ¹²⁵I-labelled insulin (100-200 µCi per µg) was prepared by the chloramine-T

method as previously described¹. Specific binding of ¹²⁵I-labelled insulin by the soluble material was measured by the polyethylene glycol precipitation method², modified slightly to increase the sensitivity of the assay¹.

The soluble insulin-binding material was subjected to electrophoresis on 5% polyacrylamide gels (12.5 cm in length) using the system of Davis³ in conditions we have previously reported¹. Following the electrophoresis, the gel was sliced and the insulin-binding activity eluted from the various gel segments as previously described¹. The binding activity was assayed in the eluates by the polyethylene glycol method² and then concentrated by ultrafiltration¹. Results were obtained using the concentrated preparations of the isolated insulin-binding species.

In the absence of insulin at 4 °C the two insulin-binding species migrate as single peaks of activity with no spontaneous formation of any significant amounts of the other binding species (Fig. 1). Thus, in these conditions both binding species are relatively stable and migrate during electrophoresis in their customary positions.

Figure 2 shows the effect of insulin. Addition of the hormone (50 ng ml⁻¹) to isolated species I (Fig. 2a) causes the appearance of a significant amount of insulin-binding material in the region occupied by species II. There is a small amount of insulin-binding material located beyond species II but this small insulin-binding peak is inconsistently found and its significance is not clear. In contrast to the findings with isolated species I, addition of insulin to isolated species II (Fig. 2b) fails to cause any formation of species I.

Figure 3 shows the sensitivity of the insulin-mediated conversion of species I to species II. The loss of insulin-binding activity in the position of species I is paralleled by the appearance of insulin-binding activity in species II. A significant amount of conversion is elicited by an insulin concentration as low as 0.5 ng ml⁻¹, which is well within physiological insulin levels. These findings demonstrate a direct and highly sensitive effect of insulin on conversion of the high-affinity insulin-binding activity to a low-affinity form which has a different electrophoretic mobility from the parent species.

Ginsberg *et al.*⁴, using material solubilised from turkey red cells, showed an insulin-mediated conversion of a large-form insulin-binding peak to a small form. These studies differ from our findings in rat fat cells by the demonstration that the small peak could be converted back to the large peak by insulin. Our failure to find a conversion of species II to species I either in the presence or absence of insulin may be related to the conditions used. All procedures were carried out at 4 °C, a temperature at

Fig. 1 Electrophoresis of the isolated insulin-binding species. Species I (a) and species II (b) were isolated from the Triton X-100 extract of fat cell plasma membranes and concentrated as previously described¹. Polyacrylamide-gel electrophoresis of the separate species was carried out for 3 h following a 16 h incubation period at 4 °C (ref. 1). The gels were then sliced and the gel sections eluted¹. The amount of insulin-binding activity was determined in the eluates by the polyethylene glycol method⁴.

which changes in the size of the turkey insulin receptor are slow⁴. However, the insulin-binding species isolated from rat fat cells may be quite different from those isolated from turkey red cells. For example, we isolate two insulin-binding species from the adipocyte plasma membrane, whereas only one species is initially isolated from the avian cell. In the red cell system, insulin exposure is needed before the second species is detected. The fat cell system also seems to be more sensitive to the effects of insulin. A hormone concentration of 0.5 ng ml^{-1} causes significant binding-species conversion ($\sim 30\%$) in our system, whereas a concentration of 25 ng ml^{-1} is required in the red cell extract to effect an 18% conversion to the small form. Moreover, $\sim 70\%$ of the total binding by adipocyte species I could be converted to species II, compared with a 30% conversion for the avian cell preparation.

Maturo and Hollenberg⁵ have shown the presence of two distinct insulin-binding activities in a detergent extract of rat liver plasma membrane. The large species isolated by Sepharose-6B chromatography had complicated insulin-binding properties, whereas the smaller form demonstrated a simple insulin-binding isotherm. The insulin-binding activity isolated by insulin-agarose affinity chromatography corresponded to the small form, and the large form was regenerated by the addition of a glycoprotein fraction which by itself failed to bind insulin specifically. The two forms of insulin-binding activity may correspond to species I and II which we have also demonstrated in rat liver membranes⁶. Maturo and Hollenberg⁵ and Jacobs *et al.*⁷ have found that the insulin-binding activity isolated by insulin-agarose affinity chromatography of liver extracts has hormone-binding characteristics which are similar to the binding characteristics of species II (ref. 1). This observation supports our present finding that the interaction of species I (high affinity, complex insulin-binding kinetics) with insulin (and presumably with insulin-agarose) causes a conversion to species II (low

Fig. 2 Electrophoresis of the isolated insulin-binding species in the presence of insulin. Species I (a) and species II (b) were incubated with insulin (50 ng ml^{-1}) for 16 h at 4°C . The incubation mixtures were then subjected to gel electrophoresis for 3 h. The gels were cut, eluted and insulin-binding activity determined as described in Fig. 1.

Fig. 3 Effect of insulin on the conversion of species I to species II. Species I was incubated with the indicated concentrations of insulin for 16 h at 4°C . The amount of species II formed and the disappearance of species I were determined as indicated in Fig. 1. Each point on the graph represents the mean $\pm$ s.e. of three separate experiments. The total amount of insulin-binding eluted from the gel was taken as 100%. ●, Peak I; ○, peak II.

affinity, simple insulin-binding kinetics). Thus, it may be impossible to purify the high-affinity insulin-binding component by the use of affinity columns that contain insulin.

The findings reported here emphasise the complexities which surround the interaction of insulin with the insulin receptor. The ability of insulin to induce the formation of a low-affinity component from a high-affinity binding species may help to explain the mechanisms underlying certain phenomena found in studies of insulin-binding to target cells and subcellular particles (for example, 'negative cooperativity', curvilinear Scatchard plots). In addition, the loss of insulin binding associated with high plasma insulin levels in insulin-resistant states of man and animals⁸⁻¹³ may in part be related to the insulin-mediated conversion of species I to species II. Finally, as the conversion of the high-affinity species to the low-affinity form is highly sensitive to insulin, this molecular event may represent an early step in insulin action which follows binding of the hormone to the receptor.

We thank Drs J. M. Amatruda, L. S. Jacobs and D. H. Lockwood for reviews of the manuscript. This work was supported by grants from the Juvenile Diabetes Foundation and NIH grant AM20129.

Effect of tetrodotoxin on adrenaline secretion in the perfused rat adrenal medulla

EXTRACELLULAR Ca ions are required for the secretion of many hormones¹. In the adrenal medulla catecholamine secretion evoked by acetylcholine (ACh) is completely blocked by omitting Ca from the medium^{2,3}. The mechanism for Ca entry has been studied in a pheochromocytoma cell line (PC12) which originated from a rat adrenal medullary tumour^{4,5}. Two alternative ways of Ca entry were considered, voltage-dependent Ca channels and ACh channels. By analysing dopamine secretion⁴ and radioactive Ca influx⁵ in various ionic environments it was concluded that more than 80% of the Ca ions enter through the voltage-dependent Ca channels during stimulation by cholinergic agonists. Action potentials mediated by Na^{6,7} and Ca⁷ have been demonstrated in primary cultures of rat adrenal chromaffin cells. Furthermore, extracellular recording techniques can detect spontaneous action potentials in these cells. The frequency of these action potentials is modified in a dose-dependent manner by ACh (3×10^{-7} M to 10^{-4} M)⁷, and the same range of ACh concentrations stimulates adrenaline secretion in the perfused rat adrenal medulla^{3,8}. Thus modulation of action potential frequency by ACh may be a mechanism for controlling the amount of Ca entry. The potential change during a Na action potential may activate voltage-dependent Ca channels, thereby increasing Ca influx. Also, spontaneous action potentials are blocked by 6 μ M tetrodotoxin (TTX)⁷, a specific inhibitor of Na channels⁹. Therefore, if the Na action potential is involved in secretion, TTX should reduce Ca entry which in turn should decrease catecholamine secretion. We tested this hypothesis in the perfused rat adrenal medulla and report here that TTX decreases a portion of the adrenaline secretion evoked by either high KCl or ACh. Thus, Na action potentials, by facilitating the activation of Ca channels, may be involved in the regulation of adrenaline secretion from adrenal chromaffin cells.

The technique for perfusion of the isolated rat adrenal medulla has been described by Ishikawa *et al.*³. Male rats (Sprague-Dawley, Simonsen) weighing 180–300 g were used. After ether anaesthesia an adrenolumbar vein entering the left adrenal gland was cannulated and arteries and other veins connected to the gland were ligated. The adrenal gland was then removed from the rat and maintained at room temperature

Table 1 Adrenaline release stimulated by acetylcholine (2 μ M)

Conditions during second response	Second response as a % of initial response	Third response as a % of initial response
ACh control	71 $\pm$ 3 (6)	47 $\pm$ 11 (6)
ACh + TTX (6 μ M)	41 $\pm$ 4 (6)	37 $\pm$ 6 (6)
	$P < 0.0001^*$	NS at $P = 0.2^*$
ACh + CoCl ₂ (5 mM)	0 (2)	216 (2)

Experiments were carried out as described in the legend to Fig. 1a, b except that release was evoked by three successive challenges to 2 μ M ACh. The response to the second ACh challenge is expressed as per cent of the response to the initial ACh challenge after subtraction of basal secretion. As in Fig. 1, the first and third responses were evoked in ACh alone. The total initial response to ACh was $120 \pm 13(14)$ pmol min⁻¹. The basal secretion was $30 \pm 7(14)$ pmol min⁻¹. Data are expressed as the mean $\pm$ s.e.m. with the number of adrenals indicated in parentheses. The inhibition of the response to ACh by TTX (second response) was reversible (third response). The response to ACh after removal of CoCl₂ was not only reversed but inexplicably enhanced. To prevent ACh hydrolysis eserine sulphate (1.5 μ M) was added to the saline of all experiments involving ACh.

*Student's *t*-test for comparison with the ACh control, two-tailed.

Fig. 1 a, Adrenaline release during three successive challenges with 12 mM KCl (indicated by the horizontal bars at the top of the graph). Each KCl challenge and collection period lasted 5 min. Between KCl challenges the adrenal was perfused for 10 min with normal saline. At the end of the 50 min the adrenal gland was discarded. b, Effect of TTX (6 μ M) on adrenaline release stimulated by 12 mM KCl. Conditions were identical to those of a except that TTX was present during the period indicated by cross hatching. c, Effects of TTX and CoCl₂ on adrenaline release stimulated by different concentrations of KCl. Experiments were carried out as for a and b. After subtraction of basal secretion from the stimulated secretion, the net response to the second KCl challenge is expressed as per cent of the net response to the initial KCl challenge. The second challenge contained: KCl alone (●), 6 μ M TTX (○) or 5 mM CoCl₂ (▲). The KCl concentration is plotted on a log scale. Each point with standard error bars represents the mean result from four different adrenals, except where *n* is specified by the number adjacent to the point. Points without standard error bars represent single samples. Statistically significant (Student's *t*-test two-tailed, $P < 0.05$) depression of the KCl response in the presence of TTX is indicated by an asterisk. This effect of TTX was completely reversible, as there were no statistically significant differences ($P > 0.07$) in response to the third KCl challenge between controls and adrenals which received TTX during the second challenge. The effect of 6 mM CoCl₂ was also reversible. CoCl₂ (5 mM) interfered with neither the extraction nor fluorescence of adrenaline standards or samples.

(21–23°C). Saline was perfused retrogradely through the vein and collected from a small incision on the adrenal cortex. The speed of perfusion was controlled by a roller pump at 0.15 ml min⁻¹.

Adrenaline was assayed by using a trihydroxyindole fluorometric assay¹⁰ after previous butanol extraction¹¹ of the samples. The assay is specific for adrenaline. All values are based on adrenaline standards which were carried through the entire extraction procedure for each experiment.

The normal solution used for perfusion had the following composition: NaCl 150 mM, KCl 5.6 mM, CaCl₂ 2 mM, MgCl₂ 1 mM, NaH₂PO₄ 1 mM, HEPES-NaOH 10 mM and glucose 5.0 mM. The saline was bubbled with 100% O₂. The concentration of KCl, CaCl₂ or CoCl₂ was increased by replacing an osmotically equivalent amount of NaCl.

Fig. 2 Adrenaline secretion by adrenals perfused with different concentrations of KCl and the effect of Ca. The duration of the KCl challenge and each collection period was 5 min. Adrenaline secretion at each concentration of KCl (plotted on a log scale) is presented as the amount of secretion per min. The concentration of CaCl_2 was 2 (●) or 10 mM (○). Each point represents the mean result from four different adrenals unless a different n is indicated by the number adjacent to the point. Standard error bars are also given for each point except when the standard error is less than 10 pmol min^{-1} . Basal secretion is represented by the amount of release at 5.6 mM KCl. The lines were drawn by eye.

When the adrenal gland was perfused with normal saline the basal secretion varied between preparations from <15 to 68.8 pmol min^{-1} ($24 \pm 2 \text{ pmol min}^{-1}$, mean $\pm$ s.e.m., $n = 41$). As the saline was switched to a high KCl solution the rate of adrenaline secretion increased, then returned to the original level when the perfusion solution was returned to normal saline. However, the rate of adrenaline output tended to decrease as the KCl challenges were repeated (Fig. 1a). The rate of adrenaline secretion was greater with higher concentrations of KCl (Fig. 2). The lowest concentration to evoke adrenaline secretion above the basal level was ~10 mM KCl ($39 \pm 7 \text{ pmol min}^{-1}$, $n = 8$). The adrenaline release increased exponentially to 120 mM KCl ($610 \text{ pmol min}^{-1}$ for a 10-fold KCl concentration change).

CoCl_2 (5 mM), a blocker of voltage-dependent Ca channels¹², inhibited KCl-evoked release. The inhibiting effect of CoCl_2 on KCl-stimulated catecholamine secretion has been previously reported^{4,13,14} and suggests that voltage-dependent Ca channels mediate Ca entry.

An increase in the external Ca concentration raises the activation threshold for voltage-dependent Na and Ca channels¹⁵⁻¹⁸. If voltage-dependent channels are involved in KCl-induced catecholamine secretion, raising the external Ca should shift the lowest concentration of KCl required to evoke secretion. When CaCl_2 in the saline was increased from 2.0 mM to 10 mM, the lowest KCl concentration necessary to evoke adrenaline secretion shifted from ~10 mM to between 12 and 15 mM and the slope increased to 940 pmol min^{-1} for a 10-fold KCl change (Fig. 2, dotted line). The greater slope in 10 mM Ca saline can be explained by an increased Ca influx through individual Ca channels. The shift in the lowest KCl concen-

tration was significant, as the rate of secretion was lower at 12 and 15 mM KCl in the presence of high Ca.

The participation of Na action potentials in KCl-evoked secretion is demonstrated by the effect of TTX on secretion. When 6 μM TTX was added to saline, KCl-evoked release was depressed to various degrees depending on the concentration of KCl (Fig. 1b, c). The effect of TTX is present only at lower KCl concentrations.

High KCl concentrations may stimulate the cholinergic nerve terminals which innervate the chromaffin cells and thus cause subsequent release of ACh. To rule out such an indirect effect of KCl, atropine-sulphate (10 μM), an inhibitor of the muscarinic ACh receptor, was added to the saline of all experiments involving stimulation by KCl. This concentration of atropine completely blocked stimulation of adrenaline release by 2 μM ACh (see below) and ACh stimulation of action potential frequency⁷. Although the ACh receptors on the rat adrenal chromaffin cell are predominantly of the muscarinic type⁷, we have additionally confirmed that the above inhibitory effects of TTX on 15 mM KCl stimulation of adrenaline secretion still occur in the presence of high concentrations of both nicotinic and muscarinic antagonists (500 μM hexamethonium bromide + 50 μM atropine sulphate). Thus, the effect of TTX on KCl-evoked adrenaline release is due to a direct effect on the chromaffin cell.

The natural stimulus for adrenaline secretion is ACh, which is released from the splanchnic nerve terminals. We therefore tested the effects of TTX on ACh-stimulated secretion. The addition of ACh (2 μM) to saline increased adrenaline secretion ($120 \pm 13 \text{ pmol min}^{-1}$, $n = 14$). This ACh-stimulated secretion was blocked by 10 μM atropine sulphate. When TTX (6 μM) was added with ACh (2 μM), the rate of adrenaline secretion decreased to 58% of the control (Table 1).

A TTX-resistant, Co^{2+} -sensitive component of adrenaline secretion is present during stimulation by 2 μM ACh and at all levels of KCl stimulation. This stimulation is probably due to the direct activation of voltage-dependent Ca channels. The effect of TTX on KCl-evoked and ACh-stimulated adrenaline secretion is likely to be due to the specific effect of TTX on Na channels in the chromaffin cells. One possible explanation for the involvement of Na channels in secretion is that Ca ions may enter the cell through the Na channel¹⁹. As CoCl_2 (5 mM), an inhibitor of the Ca^{2+} but not the Na^{20} channel, completely blocked KCl (Fig. 1c) and ACh (Table 1) stimulated release, this seems unlikely. Alternatively, a relatively small depolarisation by KCl or ACh probably stimulates Na action potentials which serve as a trigger for further activation of voltage-dependent Ca channels.

The effect of TTX on secretion is larger at low KCl concentrations and is eventually lost as the KCl concentration is increased. One explanation is provided by the different inactivation characteristics of the Na and Ca channels. Voltage-dependent inactivation of Na channels generally occurs rapidly²¹ whereas Ca channels allow Ca ions to enter the cell for prolonged periods even at large levels of sustained depolarisation^{22,23}. Second, analysis of cultured adrenal chromaffin cells indicates that a low concentration of KCl (11.6 mM) produces an increase in action potential frequency which is sustained for the duration of perfusion with KCl (5 min). With a higher concentration of KCl (15.6 mM) the frequency of action potentials increases initially then gradually decreases to basal level⁷. Thus, the total number of action potentials during a 5-min application of KCl may be larger in 11.6 mM than in 15.6 mM KCl. Such an effect would diminish the relative contribution of the Na action potential as the KCl concentration is increased.

These results conflict with previous studies on the PC12 clonal cell line. PC12 cells have Ca^{2+} and Na^{24} (TTX-sensitive) action potentials. Although direct activation of voltage-dependent Ca channels by KCl or cholinergic agonists contribute to Ca influx⁵ and catecholamine secretion^{4,25}, TTX has no effect on either Ca influx or secretion. As cells *in situ* may be under the influence of

circulating hormones and other factors²⁶, their properties could be different from those of cell lines.

In view of the partial inhibition by TTX of adrenaline release from the adrenal medulla we propose that the Na action potential, by facilitating the activation of a voltage-dependent Ca channel, may have a regulatory role in catecholamine release. The facilitatory effect of the Na action potentials on secretion occurs at the level of the chromaffin cell membrane and is only detectable at low levels of depolarisation. Na action potentials seem to have a similar function in pancreatic β cells, where 37% of the first phase of insulin secretion evoked by glucose is blocked by TTX²⁷.

We thank Dr K. Ishikawa for participating in preliminary experiments, and Drs T. Kanno, S. F. Heinemann, J. Patrick, D. Schubert, W. Stallcup, J. H. Steinbach and M. Yoshii for criticism. The research was supported by grants from the Parrott Foundation, NIH grant NS 11918, and NIH Career Development Award NS 00102 to Y.K., and NIH grant NS 09012 to S.H. A.K.R. was supported by a postdoctoral fellowship from the American Heart Association.

Thyroid hormone induces competence for oestrogen-dependent vitellogenin synthesis in developing *Xenopus laevis* liver

OESTROGEN-DEPENDENT synthesis of vitellogenin, the precursor of the major yolk proteins, in the liver of egg-laying vertebrates is an attractive model for investigating regulatory mechanisms of gene expression. Induction of vitellogenin synthesis by oestrogen occurs not only in the liver of females but also in males which normally do not produce this protein, thus showing that responsiveness to oestrogen is not linked to sex (for review see ref. 1). However, Follet and Redshaw² reported that

Fig. 1 Detection of vitellogenin in the blood plasma of normal *Xenopus laevis* larvae by rocket immunoelectrophoresis. Blood samples were collected from normal (a) and oestrogen-treated larvae (b) after anaesthesia with 1:1,000 MS 222 solution (Tricaine methanesulphonate; Sandoz) by heart puncture. For each stage, designated according to the scale of Nieuwkoop and Faber⁶, 3-5 μ l samples from four or five animals were pooled, centrifuged and the plasma used for immunological analysis. Rocket immunoelectrophoresis⁵ was performed in 55 $\times$ 205 $\times$ 1 mm 1% agarose gel (Sigma) in 0.02 M barbital buffer (pH 8.6) containing monospecific antivitellogenin antibody diluted 1:15. Vitellogenin antibody was raised in a rabbit by subcutaneous injection of 1 mg purified vitellogenin and Freund's complete adjuvant, followed by two boosters of 0.5 mg vitellogenin each 10 and 75 days respectively after the first injection. By adsorbing the rabbit antiserum with blood plasma from unstimulated male *Xenopus* it was possible to eliminate nonspecific components and to obtain a monospecific antivitellogenin antibody, as revealed by the Ouchterlony test (data not shown). To each well 10 μ l of blood plasma, diluted 1:1 with barbital buffer, were applied and electrophoresis performed at 4°C, beginning at 10 V for 30 min, and thereafter at 30 V for 17.5 h; after the initial 2 h 10 μ l of barbital buffer were added to each well. After electrophoresis the gels were washed successively in 0.9% NaCl and distilled water. After drying they were stained for 10 min in 0.5% Coomassie brilliant blue and destained in the solvent containing ethanol, distilled water and acetic acid. Arabic numerals give stages according to Nieuwkoop and Faber⁶, representing prometamorphic tadpoles (56/57), actual transformation of tadpoles (66-66) and postmetamorphic froglets (>66). M, vitellogenin marker. The broad and diffuse rockets obtained with the marker protein and blood plasma of later developmental stages are caused by excessive amounts of vitellogenin and do not reflect heterogeneity of the proteins.

liver of *Xenopus laevis* larvae is refractory to oestrogen, becoming responsive shortly after completion of metamorphosis. As amphibian metamorphosis is known to be obligatorily dependent on thyroid hormones (for review see ref. 3), the question arises as to whether acquisition of competence to respond to oestrogen by the *Xenopus* liver cells is part of the hormonally regulated metamorphic changes or merely reflects age-dependent maturation. Here we present evidence that during normal development of *Xenopus laevis* the liver cells become responsive to oestrogen during metamorphosis and before vitellogenin synthesis has been initiated by endogenous oestrogens. Moreover, we demonstrate that responsiveness to oestrogen fails to appear when metamorphosis is suppressed, but readily appears after induction of metamorphosis by thyroxine, suggesting that acquisition of competence to respond to oestrogen by the *Xenopus* liver cells is controlled by thyroid hormones.

Responsiveness to oestrogen was tested by the appearance of vitellogenin in the blood of tadpoles stimulated by oestrogens either continuously or for periods of 7 days, as described in

Table 1 First appearance of vitellogenin in the blood and of the response to estrogen by liver cells during normal development of *Xenopus laevis*

	Stage; age	Vitellogenin-positive samples as % of (total)						
		56/57; 39	60; 46	62; 49	64; 53	65 ⁻ ; 54	65 ⁺ ; 56	≥66; 58-92
Control		0% (6)	0% (6)	0% (10)	0% (8)	50% (8)	80% (10)	25% (20)
Oestradiol-3, 17 β		0% (3)	0% (3)	15% (6)	100% (5)	100% (3)	100% (8)	100% (15)
Ovocyclin		0% (3)	0% (3)	15% (6)	100% (4)	100% (4)	100% (8)	100% (15)

Tadpoles of *Xenopus laevis* were obtained by induced breeding and reared in standard conditions⁷. To test for responsiveness to oestrogen they were exposed either continuously from stage 49 onwards or for 7 days to oestradiol-3,17 β (Merck) or Ovocyclin (1 part oestradiol-3-benzoate + 3 parts oestradiol-3-benzoate-17-acetate) (Ciba-Geigy) each at a concentration of 5 μ g per 100 ml water. Age refers to days after hatching.

Table 1 legend. In agreement with an earlier report of Gallien⁴ continuous treatment resulted in sex reversal in genetic males, yielding 100% females as judged from a random sample of 22 autopsies. Without oestrogen a normal sex ratio of tadpoles was found as shown by the proportion of 32 females:31 males determined in a randomly selected sample. Vitellogenin was detected in the plasma of pooled blood samples by rocket immunoelectrophoresis⁵, as described in Fig. 1 legend.

In a first experiment, involving three different batches of tadpoles, we investigated the first appearance of vitellogenin and the earliest response to oestrogen by the liver in normally developing tadpoles. A typical result of the immunoelectrophoretic analysis is given in Fig. 1, which shows the specificity of the immunological reaction. The height of the precipitation peaks is an indication of the vitellogenin concentration in the blood plasma. The results of these analyses are summarised in Table 1. During normal development and in the absence of extraneous oestrogen vitellogenin is already detectable during

late metamorphosis, stage 65/66 (ref. 6). As there is a 50%:50% distribution of males and females in this group, pooling of blood samples results in a dilution of vitellogenin. Therefore the possibility that synthesis of this protein might be initiated at an even earlier stage is not excluded. In contrast to Follet and Redshaw² who considered the appearance of vitellogenin synthesis to be a post-metamorphic event, our results provide good evidence that this change in biosynthetic activity of the larval liver cells is part of the metamorphic transformation. We assume that this discrepancy might be caused by differences in sensitivity of the methods used for detection of vitellogenin. Figure 1a and Table 1 show reduced levels of vitellogenin and a decrease in the relative number of vitellogenin-positive blood samples from 80% to 25% in newly metamorphosed froglets, suggesting vitellogenin utilisation by the first generation of growing oocytes.

To determine the stage of onset of competence to respond to oestrogen in the larval liver, blood samples of oestrogen-stimulated tadpoles were analysed. Except for sex reversal in genetic males, oestrogen treatment had no visible morphogenetic effect nor did it alter the rate of development. A representative experiment is shown in Fig. 1b, demonstrating precocious appearance and higher levels of vitellogenin in the blood of oestrogen-treated tadpoles. The corresponding results, summarised in Table 1, clearly reveal that oestradiol-3,17 β and Ovocyclin applied in water were equally efficient in inducing vitellogenin synthesis as early as stage 62. No differences in timing and extent of response were noted between continuous and short-term treatment by oestrogen. Thus during normal development of *Xenopus laevis* the competence of larval liver cells to respond to oestrogen is apparently established during metamorphosis, before vitellogenin synthesis has been induced by endogenous oestrogen.

To establish whether the onset of responsiveness of the larval liver to oestrogen is dependent on thyroid hormone, the response to oestrogen was followed in thyrostatic tadpoles, developmentally arrested at stage 56, between 65 and 85 days after hatching and in a group of thyrostatic tadpoles, induced to metamorphosis by L-thyroxine at 78 days after hatching. Typical immunological tests are shown in Fig. 2 and a summary of the analyses is presented in Table 2.

Thyrostatic tadpoles in which metamorphosis had been suppressed failed to respond to effective levels of oestrogen, even at an age when normally developing animals had become fully responsive to this hormone. However, treatment of thyrostatic tadpoles with 10⁻⁸ M L-thyroxine at an age at which normally-developing sibling larvae (Table 1) had already completed metamorphosis not only induced morphological transformation but also elicited responsiveness to oestrogen. As in normal development, vitellogenin synthesis is detectable earlier in oestrogen-treated animals than in controls, suggesting that also during thyroxine-induced metamorphosis, competence to respond to oestrogen in liver cells is established before effective concentrations of oestrogen are secreted.

To our knowledge these results are the first demonstration that acquisition of competence for oestrogen-dependent synthesis of vitellogenin by the larval *Xenopus* liver is obligatorily dependent on thyroid hormone. However, it is not yet clear whether this maturative event reflects a direct or an indirect effect of the hormone. As it is generally assumed that

Fig. 2 Detection of vitellogenin in the blood plasma of thyrostatic tadpoles (left) and during thyroxine-induced metamorphosis (right). a, No oestrogen; b, with oestrogen. Further explanations as for Fig. 1.

Table 2 Absence of response to oestrogen in thyrostatic tadpoles and its induction by L-thyroxine

Thyrostatic-tadpoles				
	Vitellogenin-positive samples			
	Stage; age	56; 45-58	56; 64-68	56; 75-85
Control		0% (10)	0% (5)	0% (10)
Oestradiol-3, 17 β		0% (10)	0% (10)	0% (10)

Thyroxine-induced metamorphosis				
	Vitellogenin-positive samples as % of (total)			
	Stage; age	60; 85	62; 97	65/66; 105
Control		0% (5)	0% (5)	33% (18)
Oestradiol-3, 17 β		0% (5)	100% (5)	100% (10)

Thyrostatic animals were obtained by raising tadpoles from stage 52 onwards in a solution containing 0.4% thiourea which causes developmental arrest at stage 56 without inhibiting further growth⁸. To induce metamorphosis thyrostatic tadpoles were transferred to 10⁻⁸ M thyroxine (sodium salt, Fluka), which causes a slightly delayed but otherwise normal metamorphosis. Other details as for Table 1.

the effects of steroid hormones are mediated by cytoplasmic and nuclear binding proteins^{9,10}, the larval *Xenopus* liver because of its hormone-dependent maturation of oestrogen sensitivity, provides an ideal model for study of the molecular basis of competence and the primary events of the interaction between oestrogens and target cells.

We thank Dr R. A. Wallace for purified vitellogenin, Professor H. Fey and Miss H. Pfister for preparation of the antibody and advice on immunological procedures, and Mrs A. Rohner for technical assistance. This work was supported by the Swiss NSF (grant 3.641.75).

Note added in proof: After this paper had been submitted, a similar study was published by Knowland¹¹ indicating that liver explants of *Xenopus* larvae can be induced *in vitro* to synthesise vitellogenin as early as stage 57, but that the appearance of responsiveness is not influenced by oestrogen.

Identification and change of collagen types in differentiating myoblasts and developing chick muscle

COLLAGEN is the major structural protein in the supporting and connective tissues. In addition to its mechanical properties it has been considered to be involved in developmental processes¹⁻³. Previous studies on muscle development have concentrated on the contractile components but more recently there has been a realisation of the significance of connective tissue in this process. For example, *in vitro* studies have demonstrated the importance of a collagen substrate in promoting myoblast

Fig. 1 SDS-polyacrylamide gel electrophoresis patterns showing the presence of type I, type III and type V collagen in 1 M NaCl precipitate from pepsin-solubilised intramuscular collagen from 1-week-old chick limb. Track 1 depicts type I (ratio $\alpha 1/\alpha 2 = 2.2$) and type V collagen; track 2 shows an increase in the $\alpha 1(I)$ band (ratio $\alpha 1/\alpha 2 = 2.8$) due to the presence of $\alpha(III)$ following incubation with dithiothreitol; track 3 shows resolution of $\alpha 1(I)$ and $\alpha(III)$ using a modified interrupted electrophoresis technique¹⁹.

differentiation⁴, and more recently it was shown that all types of collagen were equally effective⁵. Mayne *et al.*⁶ demonstrated that clones of chick muscle cells were capable of synthesising type I collagen. Ketley *et al.*⁵ confirmed the synthesis of type I collagen and also reported that the collagen in intact chick muscle was solely of this type. On the other hand, Duance *et al.*⁷ and Bailey and Sims⁸ investigated the distribution of the genetically different collagen types within bovine muscle connective tissue and showed by biochemical and immunofluorescent techniques a specific distribution of the isomeric forms of collagen in this tissue. Here we report our studies on the development of chick skeletal muscle which were designed to investigate some pertinent points: (1) the distribution of collagen types in chick muscle; (2) the role of collagen in the development of muscle as a functional tissue; (3) the cellular derivation of these different collagens. Chick muscle was chosen, first, because much is known about its development and differentiation *in vitro*, and second, because it is possible to manipulate its early development in the embryo *in vivo*^{9,10}. We have isolated three isomeric forms of collagen from chick muscle, and using immunofluorescent techniques demonstrate a specific distribution of these collagen types within this tissue. Finally we have used *in vitro* muscle cell culture to examine how this distribution is achieved by temporal transitions in synthesis. These results suggest that collagen has a subtle role in the development of muscle.

Seven-day-old chick leg muscle was homogenised and the myofibrillar protein was removed by extensive washing. The insoluble intramuscular collagen was digested with pepsin and the solubilised collagens separated by fractional salt precipitation as described previously^{7,8}. Identification of the collagen types was achieved by SDS-polyacrylamide gel electrophoresis (PAGE). Antibodies to the collagen types I and III were raised in New Zealand White rabbits following injection at fortnightly intervals in Freund's adjuvant. Type-specific antibodies were obtained using immunoabsorbent columns to remove nonspecific antibodies as described previously⁷. The sections cut from the leg muscles of chicks were stained with anti-type I or III chick collagen, followed by fluorescein-conjugated anti-rabbit IgG. Rabbit anti-human type V antibodies were found to cross react with chick type V and were therefore used in this study. (We use the term type V to refer to the new type of collagen described by Burgeson *et al.*¹¹ which consists of αA and αB chains, although the molecular compositions as $[\alpha B]_2\alpha A$ (ref. 12) or $[\alpha B]_3$ and $[\alpha A]_3$ (ref. 13) have not been resolved.)

Myoblasts obtained from the thigh muscles of 13-d chick embryos were cultured for 10 d at 37°C on collagen-coated (rat tail tendon collagen) Sterilin dishes. The synthesis of collagen was demonstrated by the incorporation of ³H-proline

Table 1 Detection of collagen types by haemagglutination titres

Day	0	1	2	3	4	5	6,7	8	9,10
Type I collagen									
Haem titre	0	0	0	0	1/2	1/2	1/4	1/8	1/8
Type III collagen									
Haem titre	0	0	0	1/2	1/2	1/4	1/16	1/6	1/16
Type V collagen									
Haem titre	0	1/32	1/32	1/64	1/32	1/64	1/512	1/128	1/128

Myoblast culture: 13-d embryo thigh muscle was dissociated using 0.25% trypsin in Earle's balanced salt solution (Flow) for 40 min at 37 °C. After centrifugation the pellet was resuspended in minimal essential medium supplemented with 10% horse serum, 5% chick embryo extract, 500 IU ml⁻¹ penicillin, 500 µg ml⁻¹ streptomycin (Flow), and 50 µg ml⁻¹ ascorbic acid (BDH). Fibroblast contamination was minimised by the 'selective settling' procedure of Yaffe¹⁷ using a type I collagen (rat-tail tendon) coated vessel and incubating at 37 °C for 40 min. Cells were plated at 9.0 × 10⁵ cells ml⁻¹ on 60-mm Nunclon dishes (3 ml) or 50-mm type I collagen (rat tail tendon) coated Sterilin dishes (2 ml) and incubated at 37 °C in a 5% CO₂/95% air atmosphere. The culture medium was replaced every 24 h. Haemagglutination: the culture medium was diluted 1:5 with phosphate-buffered saline and bound to tannic acid-treated sheep red blood cells by the method of Herbert¹⁸. Types I, III and V collagen coated cells were similarly prepared using 10 µg collagen per ml 3% cells. 50 µl of a 2% suspension of coated cells was incubated at 4 °C overnight with anti-type I, III and V collagen. Uncoated cells were used as controls.

into the medium and the determination of ³H-hydroxyproline on the amino acid analyser. The radioactive collagens isolated from the cultures following pepsin treatment were analysed for collagen types by SDS-PAGE. Analysis for the presence of the different types of collagen was also carried out by both the passive haemagglutination and haemagglutination-inhibition techniques.

In these studies we have established that chick muscle is similar to human and bovine muscle in containing collagen types I, III and V (Fig. 1). Immunofluorescence localisation studies have demonstrated the presence of type I mainly in epi- and perimysium, type III in the perimysium and type V in the endomysium (Fig. 2).

The initial studies on cultures of myoblasts *in vitro* using a ³H-proline label demonstrated the synthesis of collagen and that the majority of the collagen was in the medium, in agreement with studies by Lipton¹⁴. Analysis by SDS-PAGE demonstrated the presence of type I collagen but the ³H-activities of the type III and type V collagen bands on the gel were too low to confirm their presence. However, by using the more sensitive haemagglutination and haemagglutination-inhibition assays we were able to demonstrate the presence of all three types of collagen in the medium. The myoblasts fused to form myotubes on the fourth or fifth day in culture. By sequential analysis from day 1, we were able to demonstrate temporal transitions in the nature of the collagen in the medium (Table 1). Thus type I and type III collagen could not be detected until after myoblast fusion, whereas the type V collagen appeared during growth of the myoblasts before myotube formation. This suggests that the presence of type V is probably involved in the sequence of events leading to myoblast differentiation and could serve as a marker of differentiating myoblasts.

Similar temporal transitions of the different forms of collagen have also been observed during normal development *in vivo* at the electron microscope level. Thus, patchy areas of basement membrane appear round the myotubes when they first form in chick limbs after 6 d of incubation, but organised bundles of collagen fibres do not appear in the epi- or perimysium until after approximately 10 d of incubation¹⁰.

The cellular derivation of the different collagen types is not clear. *In vivo* the collagen could be derived from a variety of cells, and even *in vitro* the contribution from a small proportion of contaminating fibroblasts cannot be discounted. Lipton¹⁴ used several rigorous procedures to produce pure myogenic cultures and observed in the electron microscope a patchy basement membrane around myofibres only when fibroblasts

were present, although fibroblasts on their own were incapable of forming basement membrane. Therefore, either the myotubes can proliferate their own basement membrane sheath, or, as the studies of Lipton suggest, a fibroblast-myotube interaction is necessary. This interaction deserves closer examination in view of its possible role in the early development of muscle where a similar interaction between muscle and non-muscle tissue has a major role in the formation of the pattern of muscles^{10,15}. Although it has been suggested that pattern formation could be controlled by diffusible molecules¹⁶, collagen may also have a regulatory role.

Fig. 2 Immunofluorescent staining of longitudinal sections of chick muscle with anti-type I (a) and anti-type III (b) (×48). Anti-type I stains the epimysium (Ep) and to a lesser extent the perimysium (P). Anti-type III also stains the epimysium but with a different distribution of the stain from anti-type I. Internal staining of the perimysium and slight staining of the endomysium (En) is also observed with the anti-type III. Transverse sections of the chick muscle stained with anti-type III (c) and anti-type V (d) (×96). Anti-type III stains predominantly the perimysium and to a lesser extent the endomysium (En). Anti-type V staining is confined to the endomysium.

We have demonstrated a spatial distribution of the isomorphic forms of collagen in chick muscle. Furthermore, we have shown temporal transitions of these isomorphic forms *in vivo* and *in vitro*. These studies strongly suggest that there is a role for collagen in muscle development. Therefore we feel that a more detailed investigation of muscle-collagen interactions should now be undertaken to elucidate the precise role of collagen in muscle development. We are now using specific collagen antibodies to study the spatial distribution and temporal synthesis of the collagen types in embryonic muscle *in vivo*.

This investigation was supported in part by the MRC and the Arthritis and Rheumatism Council. We thank D. J. Restall and R. J. Broomfield for technical assistance and Dr I. G. Burleigh for advice.

Calcium does not inhibit active sliding of microtubules from mussel gill cilia

CALCIUM ions are probably a general regulator of the assembly state and function of most cytoplasmic microtubules, the organelles upon which processes such as cell division, transport and secretion, as well as ciliary motility, may finally depend. Ciliary activity is the best model we have of microtubule function and the cilium is the only microtubule-based system allowing extensive systematic dissection at present. We are therefore interested in the mechanism by which increasing cytoplasmic Ca^{2+} causes changes in ciliary beat parameters, particularly an arrest response in the mussel (*Elliptio* or *Mytilus*) gill^{1,2}. It is well known that the beat in cilia is the result of a sliding interaction between doublet microtubules in the axoneme^{3,4}, as can be demonstrated directly when axonemes are treated briefly with trypsin⁵. On addition of ATP the trypsin-treated axonemes no longer reactivate to beat normally; instead, they telescope apart. We demonstrate here that, although all sliding of the ciliary microtubules stops during ciliary arrest *in vivo*, the sliding interaction seen after trypsin treatment is not directly inhibited by Ca^{2+} .

The response of intact mussel gill epithelium to increasing cytoplasmic Ca^{2+} can be reproduced experimentally with isolated gill cells and also with detergent-treated models and groups of ciliary axonemes ('eyelashes')^{6,7}. We are able to identify eyelashes that originate from three ciliated cell types: lateral (L), latero-frontal (LF) and frontal (F) cells. When ATP and Mg^{2+} are added, such cell models and axonemes reactivate at about 50% efficiency. We have demonstrated previously⁶ that at 10^{-2} M, Ca^{2+} inhibits 97% of all such motility, that 50% inhibition occurs at about 10^{-4} M Ca^{2+} , and that the L-cilia are differentially inhibited at 10^{-6} M Ca^{2+} .

In this study, cilia from *Elliptio* and related species were mechanically detached from the epithelium and from isolated cells. This suspension was filtered several times through cheese-cloth and the cilia were separated from the cells in a clinical centrifuge at 600g. Cilia were then pelleted in a Sorvall HB4 rotor at 10,000g and resuspended in 1% Triton X-100 in extraction solution (30 mM HEPES, 50 mM KCl, 2 mM EDTA, pH 7.0) for 10 min. They were sedimented again, resuspended in wash solution (30 mM HEPES, 50 mM KCl) and stored on ice for further use. Axonemal protein was determined by the method of Schaffner and Weissmann⁸ using bovine serum albumin as a standard. Trypsin digestion was carried out at room

Fig. 1 Dark field images of trypsin-treated ciliary axonemes: left, before ATP addition; right, after disintegration in medium without added Ca^{2+} . $\times 2,900$.

temperature; the trypsin:protein ratio was always $\sim 1:500$. Digestion was stopped after 3 min with excess soybean trypsin inhibitor. Disintegration was followed in a drop of the solution containing trypsin-digested axonemes on a glass slide, covered with a cover slip. Reactivation solution (30 mM HEPES, 50 mM KCl, 4 mM MgCl_2 , 2 mM EGTA, 2 mM ATP, pH 7.0) was drawn in from the side by capillary action, while the axonemes were observed under dark field. Axonemes were photographed before and after ATP reached them. This procedure was carried out in the same way when 10^{-2} M CaCl_2 was substituted for EGTA in the reactivation solution.

In dark field, the axonemes resemble long bright sticks of variable length (Fig. 1). When reactivation solution was added to axonemes not treated with trypsin, they reactivated normally and beat occurred over a long period (10 min observed). Disintegration of axonemes was never found in the presence of ATP if they were treated only with detergent. However, trypsin-digested axonemes twitched briefly when the front of the ATP-containing reactivation solution reached them. Then, they either disintegrated into bundles of thinner sticks (banana peel) (Fig. 1) or elongated (Fig. 2). In many cases, the fragments curved as this occurred. Afterwards, no further movement could be observed. Elongation unequivocally represents active sliding of microtubules, but disintegration might also occur if ATP plasticises the axoneme to permit passive unrolling. Both effects can occur on one axonemal fragment. Figure 2 is the first direct dark field demonstration of sliding in a trypsin-treated metazoan somatic cell cilium.

By a differential count, we quantitated the percentage of trypsin-treated axonemes which underwent either type of movement in various conditions (Table 1). When reactivation solution without ATP was drawn through the preparation, there was almost no effect, whereas about 40% of the axonemes disintegrated or elongated in the presence of 2 mM ATP. It is difficult to separate accurately disintegration and elongation but we estimate that roughly 10% of the axonemes elongate; this varies greatly between preparations. Before addition of ATP, the longer axonemes in the field are approximately the length of L-cilia, that is 14 μm . However, it is not yet possible to determine precisely the origin of the isolated axonemes. To investigate the effect of Ca^{2+} on the sliding in these preparations, 10^{-2} M Ca^{2+} was used in the reactivation medium. The overall extent of disintegration and elongation in the preparation was

Table 1 Effect of calcium addition on amount of axonemal disintegration and sliding

	% (Disintegration plus sliding) $\pm$ s.d.		
	No ATP	ATP alone	ATP, Ca^{2+}

2 mM Mg^{2+} , ATP alone or with 10 mM Ca^{2+} added to trypsin-treated axonemes.

* 20 Experiments.

unaffected by the presence of high Ca^{2+} (Table 1). No obvious change in the relative amounts or the velocities of either of these processes was detectable. Specifically, elongation of axonemes was not inhibited. Photographic and dark field observation of digested axonemes revealed that neither the form nor the final extent of elongation (Fig. 2) was affected. Similar results were obtained when Ca^{2+} replaced both Mg^{2+} and EGTA in the reactivation solution, but preliminary work indicates that the efficiency of sliding is somewhat reduced when minimal Mg^{2+} is present.

Fig. 2 Dark field images of trypsin-treated ciliary axonemes. Sliding in medium without Ca^{2+} before (a) and after (b) addition of ATP. Sliding in medium with $\sim 10^{-2}$ M Ca^{2+} : c, axonemal length ~ 13 μm before ATP addition; d, after addition of ATP. $\times 3,100$.

These results clarify the effect of Ca^{2+} on the ciliary axonemes. The major bonds that hold the trypsin-treated axoneme together in the absence of ATP are thought to be dynein-tubulin 'rigor' type interactions, described by Gibbons and Gibbons⁹. It is known that ATP will plasticise these bonds, and this may be responsible for the disintegration seen when ATP and Mg^{2+} are added to the trypsin-treated preparations⁴. Because the amount of disintegration seen is relatively unaffected by the presence of high Ca^{2+} , we conclude that Ca^{2+} does not significantly stabilise such bonding. More importantly, Ca^{2+} , at least in concentrations approaching 10^{-2} M, does not affect form or extent of the sliding elongation seen in the trypsin-treated axonemes in the presence of ATP and Mg^{2+} . Also, the overall number of axonemes which slide in the absence compared with the presence of Ca^{2+} does not seem to change. These results make it unlikely that a small subset of doublets or arms in each axoneme is specifically inhibited by Ca^{2+} , although we cannot yet exclude this possibility. In any event, a significant proportion of mussel gill axonemes which do elongate in the presence of Ca^{2+} are likely to be L-cilia axonemes which implies that sliding is little affected by raising the free Ca^{2+} about four orders of magnitude above the concentrations at which it arrests beat. We conclude that the trypsin-resistant dynein-tubulin interactions responsible for microtubule sliding are insensitive to changes in Ca^{2+} that physiologically account for ciliary arrest.

Summers and Gibbons⁵ originally demonstrated that in trypsin-treated sea urchin sperm axonemes, reactivation with Ca^{2+} and ATP would produce sliding, but less effectively than Mg^{2+} and ATP. In *Tetrahymena*, in experiments similar to ours, Sale¹⁰ has shown that trypsin-treated axonemes slide in the presence of 1 mM Ca^{2+} and Mg^{2+} . Zanetti *et al.* (personal communication) have shown that sliding also occurs in *Tetrahymena* when $\text{Ca}^{2+} < 10^{-3}$ M is substituted for Mg^{2+} . Therefore, although these experiments are not as stringent as ours, as in life Ca^{2+} does not cause ciliary arrest in these systems, they essentially confirm our results that in trypsin-treated axonemes high Ca^{2+} has little or no effect on sliding. This is perhaps not surprising as the absence of complete arrest as a physiological effect of increasing cytoplasmic Ca^{2+} implies continued microtubule sliding. For example, in *Paramecium*, increasing intracellular Ca^{2+} to greater than 10^{-6} M causes ciliary reversal with continued beat¹¹. In *Tetrahymena*, despite such possible ciliary reversal, the direction of active sliding is unaffected by increased Ca^{2+} (ref. 10).

We also conclude that the Ca^{2+} -sensitive system responsible for ciliary arrest originally present in isolated gill cilia is destroyed by brief treatment with trypsin. Concomitantly, there is a change in ciliary behaviour such that the normal constraints on microtubule sliding disappear and the axoneme telescopes apart rather than beating. It is possible that these two effects are correlated. Any or all of three morphological components of the axoneme might be implicated in either Ca^{2+} -sensitive or Ca^{2+} -insensitive aspects of the normal control of sliding: the dynein arms themselves; the spoke, central sheath complex; and the interdoublet (nexin) links. Spokes and interdoublet links are degraded by trypsin¹², although spokes at least do not completely disappear⁴. Despite the relative stability of the dynein arms, and their demonstrable function after trypsin digestion, some regulatory component of these structures might also be degraded. Detailed study of the biochemical effects of trypsin treatment has not been undertaken and might prove profitable. Of these components, the spoke-central sheath interaction has been most directly implicated in the control of sliding, both on morphological grounds by Warner and Satir¹³, and in mutant studies¹⁴. The detailed interaction of this system with Ca^{2+} is not understood. Also, the precise mechanisms by which sliding is converted into bending and otherwise restricted or synchronised in the intact axoneme in $\text{Ca}^{2+} < 10^{-7}$ M are still unknown. When these features are more accurately specified, it should be possible to localise the site(s) of interaction of Ca^{2+} and to detect how appropriate changes in axonemal behaviour are produced by increasing axonemal Ca^{2+} .

This work was supported by a grant from the USPHS and a DAAD Fellowship to M.F.W. The work was begun at the University of California. We thank Dr S. L. Wissig for use of facilities.

Effect of modification by *N*-acetoxy-*N*-2-acetylaminofluorene on the level of DNA methylation

DNA METHYLATION in prokaryotes as well as in eukaryotes is a widely distributed phenomenon but its biological role is still unknown. In prokaryotes, DNA methylation has been related to restriction recognition mechanisms^{1,2}; no such correlation has yet been found in eukaryotes. Some investigators have suggested that cell differentiation and embryogenesis might be related to DNA methylation³⁻⁵. The recent results obtained by Christman *et al.*⁶ indicating that inhibition of DNA methylation may promote the differentiation and expression of globin genes in Friend erythroleukaemia cells, support this theory. In their observations, inhibition of DNA methylation was obtained after treatment of the cells with the methionine analogue L-ethionine which is also a carcinogen. We have used another approach where the change of levels of *in vitro* 5-methyl-³H-cytosine formation in DNA following DNA modification with a carcinogen is observed. We have chosen *N*-acetoxy-*N*-2-acetylaminofluorene (*N*-AcO-AAF) which reacts covalently *in vitro* and *in vivo* with nucleic acids and proteins⁷⁻⁹ and which, after administration to animals, induces tumours¹⁰.

The DNAs substituted mainly in position 8 of guanine moieties by this aromatic compound were used as substrates for DNA (cytosine-5) methyltransferase from rat brain tissue, an organ which exhibits high levels of methyltransferases during early postnatal development (ref. 11 and unpublished results), and has been compared to non-substituted DNA for the methyl acceptance capacity.

Table 1 The methylation of DNA modified by *N*-AcO-AAF or *N*-AcO-AAIF

Substrate	% Methylation*
Non-modified DNA	100.0
DNA-AAF; 4.0%	46.8 ± 5%
DNA-AAIF, 4.5%	37.0 ± 2.4%
DNA-AAIF, 5.8%	32.2 ± 2.2%

Unmodified or carcinogen-modified chicken erythrocyte DNAs (40 µg) were obtained as described in the legend to Fig. 2. DNA from chicken erythrocyte was modified by *N*-AcO-AAIF following the procedure previously described¹⁸. DNA substrate was incubated with DNA methyltransferase from rat brain in conditions as described in the legend to Fig. 1.

* Percentages of methylation were calculated using unmodified chicken erythrocyte DNA as control (100%). Values are from experiments made in triplicate.

The optimal conditions for the methylation of DNA by *S*-adenosyl-L-methyl ³H-methionine in the presence of rat brain DNA (cytosine-5) methyltransferase, using DNAs from chicken erythrocyte or *Micrococcus lysodeikticus* (Sigma), were first established. The substrate concentration which gave a maximal reaction velocity with 0.6 mg of brain enzyme protein was 40 µg of DNA. At this DNA concentration the maximal level of methylation was obtained after ~90 min of incubation (Fig. 1). 5-Methyl-³H-cytosine was the only methylated base found to be present in DNA reacted with the brain enzyme (data not shown).

DNAs from chicken erythrocyte or *Micrococcus lysodeikticus* were then reacted with *N*-AcO-AAF resulting in the production of carcinogen covalently bound to the guanine residue of DNA¹². By using the appropriate conditions DNA could be modified *in vitro* by the carcinogen to a varying extent. Calculations to establish the percentage of modified bases have been described elsewhere^{13,14}.

Figure 2 shows the results obtained if carcinogen-modified DNAs (DNA-AAF) were methylated in the presence of rat

Fig. 1 Methylation of chicken erythrocyte DNA by rat brain DNA (cytosine-5) methyltransferase. The standard assay mixture contained in a final vol. of 0.2 ml: 40 µg DNA, 0.35 µg pancreatic RNase, 0.4–0.6 mg enzyme protein, 2 µCi *S*-adenosyl-L-methyl-³H-methionine, 50 mM Tris-HCl pH 7.8 and 0.5 mM dithiothreitol. After incubation at 37°C for various times 0.6 ml H₂O and 1 ml of carrier calf thymus DNA solution (1 mg ml⁻¹) were added to the incubation mixture. This was then deproteinised with SDS sodium perchlorate and extracted with a mixture of chloroform-isooctyl alcohol as described elsewhere²⁵. The final DNA pellet was dissolved in 0.1 M NaOH (0.2 ml) by incubation at 90°C for 10 min. The clear solution was transferred to a scintillation vial and the radioactivity measured after complete mixing with Unisolve 1, scintillator (Koch-Light). Blank values were subtracted in each case. Averages with s.d. are from two experiments made in duplicate. Brain enzyme was prepared as follows: Sprague-Dawley rats (7-day-old) were decapitated and the brain cortices quickly removed and homogenised with buffer solution containing 2.4 M sucrose and 0.001 M MgCl₂ in a glass-Teflon Potter-Elvehjem homogeniser to a final volume of 10 times the tissue weight. The remaining procedure was similar to that described by Pogo *et al.*²⁶. All operations were carried out at 4°C unless otherwise stated. Protein concentration was determined according to Lowry *et al.*²⁷ using bovine serum albumin as standard. Chicken erythrocyte DNA was obtained using the procedure described elsewhere²⁸.

brain DNA methyltransferase. An inverse relationship between levels of DNA methylation and the percentage of modified bases residues in the DNA structure was observed. The inhibition of DNA methylation cannot be attributed to the presence of free carcinogen in the reaction mixture as any unreacted carcinogen was removed from the DNA solution.

Similar results obtained using carcinogen-modified DNAs from two sources having a different GC content showed that inhibition of DNA methylation is independent of the nature of DNA used.

We also modified DNA with *N*-AcO-AAIF (DNA-AAIF) which is the 7-iodo derivative of *N*-AcO-AAF. Fuchs *et al.*¹⁵⁻¹⁸ reported that in DNA-AAIF the iodo-fluorene ring lies along the phosphate-sugar backbone of the double helix (outside binding model) whereas in DNA-AAF the fluorene ring is inserted between the adjacent base pairs (insertion-denaturation model). Therefore, we tested DNA-AAIF to see whether the different positioning of the fluorene residue could diversely affect the methyl accepting properties of nucleic acid. As shown in Table I, the iodo derivative substituted DNA behaved in a way similar to DNA-AAF, showing that different positioning of the fluorene ring within the DNA molecule does not change its inhibitory properties.

Fig. 2 The methylation of *in vitro* modified DNA-AAF: *N*-AcO-AAF was synthesised by a modification of the original procedure²⁹ consisting of direct hydrogenation and acetylation of 2-nitrofluorene¹⁸. The purity of the *N*-AcO-AAF obtained was checked by thin-layer chromatography and the final product was stored at -20°C as alcoholic solution. DNA bound to the carcinogen was prepared as described elsewhere¹⁴. The *in vitro* methylation reaction of carcinogen modified chicken erythrocyte or *Micrococcus lysodeikticus* DNAs were done as described in the legends to Fig. 1. The results are expressed as percentage relative to control (100%) determined with non-modified DNA. Blank values were subtracted in each case. Δ , Chicken erythrocyte DNA; $\square$, *Micrococcus lysodeikticus* DNA. Averages with s.d. are from four experiments made in triplicate except for the experiments with 11, 3 and 13% modified bases, which are in duplicate.

Arylamidation of the C8 of guanine by some aromatic amines induces a rotation of the bases involved in the double helix, altering its normal conformation and carrying a local destabilisation of the DNA^{13,19}. As shown previously, this local denaturation may change some biological properties of nucleic acids by inducing cell transformation¹⁰, premature termination of transcription at (or near) the site of DNA modification²⁰ and more recently *in vitro* inhibition of DNA synthesis²¹. Our results show that modification of guanine residues in position 8 impairs another biological property of the double helix.

The carcinogen mediated effect on DNA methylation can be explained as follows: binding of methyltransferase near or at the position of methylation in DNA may be hampered by the presence of carcinogen-modified guanines paired to cytosine residues susceptible to methylation. Consequently, DNA methylation is now restricted to cytosine residues paired to guanines which are recognised by the enzyme but which are not modified. Alternatively, it can be proposed that binding of the enzyme to DNA is not affected by the presence of carcinogen, but, subsequent walking of the enzyme on the DNA helix is interrupted by the carcinogen. The last alternative agrees with the proposed mechanism of action described for DNA (cytosine-5) methyltransferase²²⁻²⁴ as well as with the model explaining the premature termination of DNA transcription in DNA-AAF²⁰.

Further work is required to establish whether DNA under-methylation caused by aromatic amides *in vitro* can also be obtained *in vivo*, and to demonstrate the effect of DNA hypomethylation on cell differentiation and/or carcinogenesis.

We thank Professor M. Daune for hospitality and criticisms; also Dr R. P. P. Fuchs for discussions, and *N*-AcO-AAF. This work was supported by the Ligue Nationale Française contre le

Corrigenda

In the letter 'Speciation of dissolved iodine in estuarine waters' by J. D. Smith and E. C. V. Butler, *Nature* **277**, 468-469, the values for iodine in the Yarra River estuary in the text and Fig. 1 should all be multiplied by 0.73.

In the letter 'Opposing effects of tumour promoters on erythroid differentiation' by R. M. Miao *et al.*, *Nature* **274**, 271 (1978), all concentrations of 12-*O*-tetradecanoyl-13-acetate (TPA) should be 1,000-fold lower than stated; for example, 10^{-7} M should read 10^{-10} M.

Errata

In the letter 'Immunological properties of the surface of parasitic nematodes' by C. D. Mackenzie, P. M. Preston and B. M. Ogilvie, *Nature* **276**, 826-828 (1978), the following acknowledgement was omitted: 'P. M. Preston was financed by a grant from the World Bank/UNDP/WHO Special Programme for Research and Training in Tropical Diseases.'

In the letter 'Measurement of carbon tetrafluoride in the atmosphere' by R. A. Rasmussen *et al.* *Nature* **277**, 549-551, for % read p.p.t. (parts per 10^{12}), and in paragraph 8, line 8, for p.p.b. read p.p.t.

MACMILLAN BOOKS FOR STUDENTS

General Microbiology Fourth edition **Roger T. Stanier, Edward A. Adelberg & John L. Ingraham**

Retains the basic organisation of previous editions, but has been extensively revised and rewritten to take account of new discoveries and interpretations which have arisen in the last six years.

£9.95 0 333 22014 5

Steady State Enzyme Kinetics **Stanley Ainsworth**

A thorough introduction to steady-state enzyme kinetics for advanced undergraduates and upwards, which identifies the basic ideas of the subject for the reader who can apply them to any problem he is likely to meet. The book requires only an elementary acquaintance with algebraic manipulation.

£10.00 0 333 15008 2

The Heavy Transition Elements **S. A. Cotton & F. A. Hart**

This book, the most up-to-date work on this subject area, contains a detailed account of the chemistry of the 4d and 5d series of transition metals (Zr to Ag and Hf to Au), together with a substantial discussion of the lanthanide and actinide elements.

Hardcover £8.95 0 333 18665 6;
Paperback £4.95 0 333 17090 3

Biochemistry of Parasitic Protozoa **W. E. Gutteridge & G. H. Coombs**

An introduction to the biochemistry of parasitic protozoa, with a resumé of our present knowledge of drugs useful in treating diseases caused by these organisms.

Hardcover £10.00 0 333 19818 2;
Paperback £4.95 0 333 22779 4

An Introduction to Cancer Medicine **Kenneth C. Calman & John Paul**

This integrated textbook of cancer medicine covers both the scientific basis of the disease and also the principles of its clinical management.

Hardcover £8.00 0 333 21277 0;
Paperback £3.95 0 333 21278 9

The Physiology of Nematodes

Second edition

D. L. Lee & H. J. Atkinson

Much has happened in the field of nematode physiology in the ten years since the first edition of this book was published, and thus all chapters have been extensively revised, and new chapters included. Written principally for undergraduate and postgraduate students, this will also be useful for the many research workers who see the nematode as an exciting and challenging animal suitable for many fields of fundamental and applied research.

Gene Expression: Volumes 1, 2 and 3

by B. Lewin, *Massachusetts Institute of Technology.*

Volume 1: Bacterial Genomes

Contents: Synthesis of Proteins; The Genetic Code; Synthesis of the Polypeptide Chain; Punctuation in the Message; Ribosome; Transfer RNA; Control of Transcription; Transcription of Phage Genomes; The Lactose Operon; Operon Control Circuits; Expression of the Operon; Reproduction of DNA; Replication of the Bacterial Genomes; Modification and Repair of DNA; Recombination between DNA Duplexes; The Cell Division Cycle.

June 1974 660 pages
0471 53167 7 Vol. 1 (cloth) \$34.50/£15.00
0471 53168 5 Vol. 1 (paper) \$13.80/£6.00

Volume 2: Eucaryotic Chromosomes

Contents: Organization of the Genetic Apparatus; Structure of the Chromosome; Chromosome Functions during the Cell Cycle; Protein Components of the Chromosome; Sequences of Eucaryotic DNA; Expression of Genetic Information; Transcription and Processing of RNA; Control of Transcription; Interactions between Nucleus and Cytoplasm; References; Index.

September 1974 484 pages
0471 53164 2 Vol. 2 (cloth) \$29.20/£12.70
0471 53166 9 Vol. 2 (paper) \$12.90/£5.60

Volume 3: Plasmids and Phages

Contents: Transformation; Conjugation; Plasmids; Phage Lambda; Infective Pathways; Phage Lambda: Development; Phage T4; Phages T3 and T7; Single Strand DNA Phages; RNA Phages; Index.

June 1977 942 pages
0471 53170 7 Vol. 3 (cloth) \$43.20/£24.15
0471 02715 4 Vol. 3 (paper) \$20.70/£10.30

Dictionary of Microbiology

by P. Singleton and Diana Sainsbury.

Attempts to produce a compact source of readily available and up to date information for undergraduates and postgraduates in microbiology. The dictionary covers terms, concepts, techniques, tests, and other topics, and includes over one thousand microbial taxa. The entries relate to pure and applied microbiology, biochemistry, immunology, genetics, and to the microbiological aspects of allied subjects such as medicine, veterinary science and plant pathology.

November 1978 490 pages
0471 99658 0 \$45.00/£17.50

Viral Infections of Humans: Epidemiology and Control

edited by A.S. Evans, *Yale University School of Medicine, USA.*

Provides a comprehensive presentation of all major viral infections of man, with major emphasis on epidemiology and control. It fits between basic texts on virology and the larger books on clinical infectious diseases.

February 1977 616 pages
0471 99435 9 (cloth) \$52.90/£23.00

0471 99706 4 (paper) \$20.60/£8.95

Available in all Wiley territories excluding Israel.

Principles of Photochemistry

by J.A. Barltrop, *Oxford University,*
and J.D. Coyle, *The Open University, Milton Keynes.*

This is a book about the electronically excited states of organic molecules — their creation and the radiative and non-radiative pathways by which they are deactivated. It is based largely on the first part of the earlier book, *Excited States in Organic Chemistry*, and it arises out of a demand for a text covering the basic principles of photochemistry in a format acceptable to students of the subject, both undergraduate and postgraduate.

December 1978 224 pages
0471 99687 4 (paper only) \$11.50/£4.95

An Introduction to Organic Chemistry

by J. Carnduff, *Dept. of Chemistry, University of Glasgow.*

Discusses topics of organic chemistry found in most GCE 'A'-level chemistry courses. Like most books in this field it covers structure, stereochemistry, nomenclature, physical properties, reactions, and some industrial applications. Unlike many other books the discussion of reactions emphasizes what happens to the electrons during reactions by explaining carefully and using systematically the representation of mechanisms by 'curly arrows' widely used by organic chemists for ionic reactions. Throughout the text the numerous problems invite the reader to think deeply about implications and extensions of facts and theories already presented, and these should be tackled as they are met.

December 1978 208 pages
0471 99647 5 (cloth) \$19.55/£8.50
0471 99685 8 (paper) \$9.10/£3.95

The Chemical Bond

by J.N. Murrell, *Professor of Chemistry, University of Sussex,*
S.F.A. Kettle, *Professor of Chemistry, University of East Anglia*
and J.M. Tedder, *Professor of Chemistry,*
University of St. Andrews.

This book, which is intended as an introduction to the subject of the chemical bond at the undergraduate level, has a development based on those concepts of the subject which can be considered important within chemistry as a whole. The validity of these concepts is examined within both the older empirical models and within the most recent quantitative calculations.

0471 99578 9 (paper) \$11.05/£4.80

Electromagnetism

by I.S. Grant and N.R. Phillips, both of *Physics Dept., Faculty of Science, University of Manchester.*

This book is intended for honours physics students at a British University or physics majors at an American University. 'A' level or high school physics and calculus are assumed, and the reader is expected to have some elementary knowledge of vectors. However, brief descriptions of the properties of differential vector operators are given at their first appearance, not as a substitute for a mathematical text, but to remind the reader what div, grad and curl are all about and to set them in the context of electromagnetism. The distinction between macroscopic and microscopic electric and magnetic fields is fully discussed at an early stage in the book. The logical arrangement of the chapters is summarised in a flow diagram on the inside of the front cover. (*The Manchester Physics Series*)

By the time the ink has dried

David W. Hughes

WHAT use is a textbook? The answer to this question depends to an extent on which side of the desk you are sitting. Cynically we could say that the main aim of the student is simply to pass the final examination. He judges the worth of the recommended textbook by its ability to help him achieve this aim with the minimum of effort. The book should contain the course material to the depth required and hopefully little other additional material and too much rigour leading to confusion. There should be a reasonable selection of examination-type questions at the end of each chapter plus answers and wherever possible worked solutions.

The lecturer approaches the book from a different standpoint. He passed all the exams a long time ago. For him the book should fill in the background to the subject, giving it roots so to speak. It should be a guide to his lectures so that the student can turn to it to clarify the difficult or unclear bits. Also it should be a stepping stone for the mind, leading the student on to more detailed studies and to the boundaries of the subject, the regions which are uncertain, the outstanding problems, the next steps in the pursuit of knowledge and understanding.

Starting near the intellectual top end of the market we have the second edition of *The New Cosmos* by Albrecht Unsöld (Springer: New York and Berlin; paperback DM37, \$18.50). This is an English translation of the 1974 German work. The book has two main audiences, the first being the final-year astronomy and astrophysics student who is looking for an overview of his subject. The fact that the book only has 451 pages is an enormous advantage here as it saves the student, especially near exam time, from the task of wading through the larger monographs. It is also an excellent kick-off point for the mathematics or physics graduate who has turned to astronomy, astrophysics, space science or cosmology as a research field. It is a comprehensive but concise introduction to these topics. The book has an abundance of clear figures and takes pains to stress the delicate balance between the advances in observational work and in theoretical studies. It is geared to the numerate student and does not shirk the responsibility of tackling properly such subjects as radiation theory, stellar interiors, galactic rotation, degenerate matter and galactic and stellar evolu-

tion. Many astronomers and astrophysicists today grew up in their subjects clutching the first edition. This new edition is for the next generation and it can be classified simply as essential reading, a Godsend for student, lecturer and research worker alike.

Moving down the scale of complexity we come to *University Astronomy*, by J. M. Pasachoff and M. L. Kutner (W. B. Saunders: Philadelphia and London; £13.50), a book which includes basic algebraic and trigonometric equations but excludes infinitesimal calculus. The authors are aiming at the science student during his first year at university and they are well on target. The book describes our modern knowledge of astronomy, fitting the latest discoveries alongside the established results. It is refreshing to notice how the authors discuss the whole spectral range of observations as they go along and don't for example relegate all the radio work to a separate chapter. It was a book full of surprises, the large majority of them pleasant ones. It was heartening to come across time and again examples of the authors' desire to stretch the student by introducing him to the problems of experimentation and theorising. The book contained many thought-provoking sections, a few examples taken randomly includes a discussion of the errors of observation and standard deviation, Occam's Razor, the futility of studying UFOs and a Martian's investigation of life on Earth. The authors don't turn their backs on the basic physics which underlies many of the facets of astronomy but explain physical concepts in a clear and concise way. Each chapter is rounded off by a summary and outline section, a collection of multiple choice review questions, discussion topics and suggestions for additional reading. The authors are to be congratulated on producing such an excellent résumé of the subject and one that, considering the self-imposed mathematical limitations, never deviates from stressing the underlying scientific principles of astronomy.

J. M. Pasachoff and M. L. Kutner have very thoughtfully produced a *Teacher's Guide to University Astronomy* (W. B. Saunders: Philadelphia and London). This contains the answers to all the questions posed in their main textbook (considering my initial comments a more appropriate title might have been *Student's Guide*). It also has a set of seven

laboratory exercises together with the addresses of the suppliers of the relevant planetary, solar and sky photographs some sample exam papers, possible syllab and lists of audiovisual aids and stockists. It is obviously geared for the American market, but don't let this put off the non-American readers.

Both *University Astronomy* and the next book under review *Astronomy Now* (by J. M. Pasachoff; W. B. Saunders: Philadelphia and London; \$11.95) come from the same stable. *University Astronomy* contains more about the Earth and relativity, and does use basic mathematical equations. *Astronomy Now* is a shorter non-mathematical version ideal for the innumerate and the mathematicophobes. It is difficult to advise you which one of these books to choose. I know that a student who does not need the algebra would automatically pick the book without it and thus avoid the confusion. But I like mathematics and physics; they add spice to astronomy and I would advise the students to buy *University Astronomy* in the hope that some of the joys of maths and physics rubbed off.

This review continues by considering four, more descriptive astronomy textbooks which have been tailored to the needs of the American university humanities and social science students who have usually to take two one-year courses (each of about 72 lectures and lasting two semesters) in natural science subjects. I need not go into details as to why astronomy should be and is in many cases an obvious choice. Many books are produced at the required level and I have often felt apprehensive about this market being flooded. But this worry is groundless because the market is enormous. R. H. Garstang (*J. Br. Astr. Assoc.* **88** 407; 1978) gives two examples. Of the 20,000 students at the University of Colorado, 1,050 are taking the astronomy course. If we select another university more or less at random we find that 2,000 students at the University of Texas are also doing elementary astronomy. It's little wonder that a fair armful of these books are published each year considering that the publishers break even point is in the low thousands.

I am confronted with *Discovering Astronomy*, by Robert D. Chapmar (Freeman: San Francisco; hardback £12.60, paperback £7), *The Restless*

Universe: An Introduction to Astronomy, by Harry L. Shipman (Houghton Mifflin: Boston and London) and *Cosmic Evolution: An Introduction to Astronomy*, by G. B. Field, G. L. Verschuur and C. Ponnampertuma (Houghton Mifflin: Boston and London). They are all the same size; one is red, the other blue, the third brown; they contain the regulation collection of colour plates (where would one be without NASA and the Hale Observatory?). They are beautifully illustrated, well indexed, glossaried and spattered with review questions, thought questions, chapter summaries, and the like. They each have their 'special way of approaching the subject'. Chapman uses the historical angle starting from Earth and the view Earth dwellers have of the sky and moving out to the Moon, Sun, planets, stars, Galaxy and Universe. Shipman states that he differs from similar texts by stressing contemporary astronomy—"the events that readers have probably heard about from the media" and by indulging in a detailed inter-comparison of the 'geological' processes that have taken place on different planets. Field, Verschuur and Ponnampertuma concentrate on the 'evolution of the Universe from the primordial big bang, through the origin of galaxies, stars and planets to the emergence of intelligent life on Earth and the search for this life elsewhere. Even with these 'different approaches' in mind I was continually struck by the overall similarities. The differences are at best marginal and in most cases simply seem to be a difference in the ordering, much more than in content. In my experience it is a very rare lecture course that starts at the beginning of a textbook and methodically works its way through chapter by chapter, so the ordering is fairly immaterial. So I have a problem, which one should I recommend? I shudder to suggest that you should resort to 'eeny, meeny, miney, mo' but this is one way out. The other is simply to buy the cheapest.

My final book is *Exploration of the Solar System* by William J. Kaufmann III (Macmillan: New York; Collier Macmillan: London; £0.00). A book mainly about planets with a little on stars and a sister to Kaufmann's 1977 book *Astronomy: The Structure of the Universe*, which was mainly about stars with a little on planets. Kaufmann's books are aimed at the same non-mathematical audience as the three mentioned above. In *Exploration of the Solar System* one feels that Kaufmann has room to spread himself. He is not restricted by space, he studies the problems, the spacecraft, the explorations, the data, the planetary features and models in detail and with thoroughness.

In general I was extremely impressed by the high standards of these books. Writing an astronomical textbook is no easy task because topic after topic is in a state of rapid development. To quote

R. D. Chapman "it is inevitable that some parts of any book will be out of date by the time the ink has dried". It must be frustrating to write a line such as "ratio of the mass of Pluto to that of the Earth = 0.1(?)" months before the mass was accurately measured due to the discovery

and observation of a satellite. But still the job needs to be done and it is refreshing to see how well it is done time after time. □

David W. Hughes is Lecturer in Astronomy and Physics at the University of Sheffield, UK.

Mathematical cosmology

Mathematical Cosmology. By P. T. Landsberg and D. A. Evans. Pp. 306. (Clarendon/Oxford University Press: Oxford, 1978.) £6.95.

ALTHOUGH the number of students taking formal courses in cosmology is tiny, most physical scientists find room in their activities to read up on it from time to time. The stumbling block to penetrating the technical literature is usually the general theory of relativity, with its mind bending concepts of curved spacetime, event horizons and singularities, not to mention punishing (as well as non-linear) mathematics. The solution to this barrier is, according to P. T. Landsberg and D. A. Evans in their *Mathematical Cosmology*, a "stage II" book, defined in their introduction to be one which goes beyond the broad qualitative outlines, but uses only simple mathematical arguments. And this means no general relativity. Although other books, such as Michael Berry's *Principles of Cosmology and Gravitation* (Cambridge University Press, Cambridge, 1976), also attempt this, Professors Landsberg and Evans give probably the first comprehensive and systematic non-relativistic treatment of cosmology.

Students familiar with Bondi's little book *Cosmology* will know how fairly elementary Newtonian ideas can lead effortlessly to the main features of relativistic cosmological models. The authors of *Mathematical Cosmology* follow the same path, but in a much more elaborate and detailed

fashion. All the basic conceptual structure is kept simple, and individual chapters can be read in isolation without difficulty. The standard Friedmann models are thoroughly discussed, and even the steady state theory gets a mention. Each chapter is terminated with a set of questions, the answers to which are provided.

Eventually, perhaps inevitably, general relativity refuses to be excluded. It starts to intrude during the discussion of light propagation, and the appearance of distant astronomical objects. However, in this limited context, without the field equations of the dynamics of the space-time itself, there is nothing terribly formidable about it, and students should be able to follow the lucid discussion easily. When horizons are finally discussed, the approach is physical rather than geometrical, and indeed, this is true of the book as a whole.

For scientists and students with a serious interest in cosmology who do not want to invest a lot of time learning differential geometry and topology, *Mathematical Cosmology* gives an excellent, clearly written and coherent account of the standard theory which is very economical on intellectual investment. It is also economical on the pocket, because at £6.95, it is rather cheap for a 306-page textbook. For students taking cosmology the hard way, it is still worthwhile background reading, and of course most of the results are identical to those of the relativistic treatment.

Paul Davies

Paul Davies is Senior Lecturer in the Department of Mathematics at King's College, University of London, UK.

Vibrations and waves

Vibrations and Waves in Physics By I. G. Main. Pp. 336. (Cambridge University Press: Cambridge and London, 1978.) Hardback £17.50; paperback £4.95.

THIS is an excellent book which can be thoroughly recommended either for use as a text for an undergraduate course introducing the student to many of the widely-pervading notions connected with vibrations and waves, or indeed for anyone who feels the need

to broaden his knowledge in this sphere. The material covered starts with free vibrations and continues through forced vibrations, anharmonic and coupled vibrations, to non-dispersive waves. After a short chapter on Fourier theory the author looks at dispersion, water waves, electromagnetic waves, and de Broglie waves, and finally covers basic ideas in the reflection, refraction, and diffraction of waves.

The book is well and carefully constructed. An example of this is the useful flow diagram near the front, showing clearly which are the parts containing the coherent development

of the basic theory and which are what the author, in his preface, terms "excursions into physics". These "excursions" demonstrate the way in which many useful results and an increased understanding of many physical phenomena may be obtained by simple order-of-magnitude calculations.

One of the best features of the book is the choice of problems at the end of each chapter. These span a wide variety of topics and put the material of the preceding chapter firmly in a physical context. In the penultimate chapter, for example, the problems include such apparently disparate topics as reflection of electromagnetic waves from a plasma, reflection and refraction of shallow water waves at a change in depth, evaluation of lattice heat capacity at low temperatures, and calculation of the Fermi energy for conduction electrons in a metal. Almost every chapter includes at least one ingenious and non-run-of-the-mill problem illustrating the application of previously presented principles in an

everyday situation. Hints for solution are given for some of the problems, and answers are provided to all numerical questions.

The similarity of both the chapter headings and the length of the book invite comparison with Pain's *The Physics of Vibration and Waves* (Wiley: London, 1976). In fact the books are very different in character, Main spending much more time on explanation, whereas Pain covers a wider variety of material with, therefore, much less explanation. The difference between the books is well illustrated by the fact that the summaries that occur at the end of each chapter in Pain are primarily lists of formulae, whereas the summaries at the end of each section in Main are primarily words.

Classical mechanics

Mechanics and Motion. By L. Mackinnon. Pp. 161. (Clarendon/Oxford University Press: Oxford 1978.) Hardback £6; paperback £3.25.

A SOUND knowledge of classical mechanics is a valuable asset to anyone studying physics, and this book attempts to deal with those branches of the subject which are most relevant to the modern physics in a university degree course. The book is based on a first-year lecture course given by the author at the University of Essex. The basic concepts of mechanics are discussed in the first chapter, after which there are chapters on rotary motion, vibratory motion, wave motion and central force motion. Finally, there is a chapter entitled "Analytical Classical Mechanics" in which the concepts of Lagrangian and Hamiltonian mechanics are introduced.

The amount of material seems to have been limited to what can reasonably be included in a lecture course of approximately 30 one-hour lectures, and within this constraint the choice of material is reasonably satisfactory. However, the level of presentation is sometimes rather superficial. For example, there is no precise definition of the centre of mass of a system of particles, and there is only the briefest mention, and then only for the particular case of the centrifugal force, that the inertial reactions on a body act through the centre of mass. The

concept of reduced mass is not discussed at all, beyond a brief statement in the conclusion to the chapter on central force motion that the source of the force is free to move. Also, the theorems of parallel and perpendicular axes for moments of inertia are quoted without proof, the proof of the parallel axes theorem being left as an exercise for the reader. As a further example in a more advanced topic, the Coriolis force is introduced by considering a very specific problem; and the general form of the force is then stated without proof, as a rigorous treatment of the equations of motion in a rotating frame of reference is not given. Even if such a detailed treatment is considered to be unsuitable in a lecture course, it should be included in a book based on that course. A similar objection can be levelled at the discussion of Fourier analysis in the chapter on vibratory motion.

Apart from these deficiencies the book is quite well written in a style which is rather less formal than that of most books on classical mechanics. Unfortunately the standard of production is lower than one would have expected from the Oxford University Press. The book is printed directly from the type-written manuscript and some of the equations are rather badly composed. This technique may reduce the cost of production slightly, but the result is visually far less attractive than a type-set book.

J. W. Humberston

J. W. Humberston is a Lecturer in Physics at University College, London, UK.

Fluid mechanics experiments

Fluid Mechanics: A Laboratory Course. By M. A. Plint and L. Bosworth. Pp. 186. (Charles Griffin: London and High Wycombe, UK, 1978.) Paperback £5.95.

THIS book describes, in a clear and interesting manner, a series of fluid mechanics experiments using low and high speed air jets, low speed and supersonic wind tunnels and a pipe flow apparatus. The low speed experiments in air include the pressure distribution around a cylinder, the lift on an aerofoil, boundary layer traverses on a flat plate and jet and pipe flow traverses. The compressible flow experiments measure mass flow and pressure distributions in convergent-divergent nozzles and look at the supersonic flow past a double wedge aerofoil. Lubrication properties of an oil wedge using a Michell bearing rig, and the properties of an air bearing are also treated.

In cases where theory depends primarily on the physics, relevant equations are derived; otherwise the necessary equations are quoted. The authors present their own results in detail and explain the reasons for any differences that occur between theory and experiment. They argue quite rightly that details of this type can help students to look critically at their own experimental results even though the apparatus may be different. The experiments are typical of those in undergraduate courses in aeronautical, mechanical and civil engineering and in some physics courses. However, they represent only a selection of the vast number of valuable undergraduate experiments in fluid mechanics and it is unlikely that the experiments at a particular university or polytechnic will coincide exactly with the authors' choice. Even so the book would be helpful as additional reading for undergraduate engineers. The book would be most useful to those who, on entering the teaching profession, require to establish a series of fluid mechanics experiments.

The book is well presented with good diagrams, and it is not in competition with other books. For completeness it could have included more on the estimation of experimental errors but this can be found in other textbooks on experimental techniques.

T. N. Stevenson is Senior Lecturer in the Department of the Mechanics of Fluids at the University of Manchester, UK.

A detached view of the Earth

Remote Sensing: Principles and Interpretations. By F. F. Sabins, Jr. Pp. 426. (Freeman: San Francisco and Reading, 1978.) \$25; £14.50.

To the casual or unwary would-be customer the title of this large new volume suggests a comprehensive treatment of the explosively expanding modern science, remote sensing of the environment. This is an impression which would not be properly rectified by a reading of the Preface, in which the author confesses that "... because I am a geologist by training and early experience, there is a tendency (in this book) to emphasise the geologic aspects of image interpretation". Nor would it be clear from the nearby statement that "This book is designed for a one-semester or one-quarter course for upper-class or graduate students with no previous training in remote sensing" that the treatment is, in fact, very heavily biased towards the needs of the student of geology, as distinct from his colleagues in environmental science, geography, and allied fields.

To some potential purchasers, this could prove to be a very valuable volume, selecting and synthesising smoothly from the physical bases on which environmental remote sensing rests, by way of the wide variety of means by which different statements of the targets of remote sensors are acquired and analysed, to some of the chief spheres of remote sensing data applications. However, if one's interests are not predominantly concerned with the ways analyses of spacecraft (especially Landsat) data may supplement the longer-established practices of photogeology using images from aircraft and balloons, purchasing this book could be a costly mistake.

My own view is that the confessed "tendency to emphasise ... geologic aspects" is an exceptional understatement, given the breadth of cover suggested by the title. Certainly, the author does not spend all his time discussing geological phenomena, for there are useful sections on water and ice, but other classes of phenomena with which a more broadly-based student would be significantly concerned—including other surface features such as snow, land use and crops, natural vegetation, and settlements, and atmospheric phenomena such as energy budgets, cloud organisations and winds—are treated very cursorily indeed. One notable example concerns applications of remote sensing

techniques in land-use studies: this vitally-important field, full of economic and humanitarian potential, is credited with less than three pages of text. The atmosphere is ignored to such an extent that thermal infrared imagery from meteorological satellites is said to be useful for many applications—but none of those mentioned are atmospheric. Indeed, it is stated that "Clouds and surface winds ... produce confusing patterns" in such images, and that such factors must be considered (as complicating factors) by the

(surface) interpreter. Such a treatment is scarcely fair when the primary purposes of these satellites are recalled.

Had this textbook been entitled *Satellite Remote Sensing for the Geologist*, I would have applauded it; as it is, I cannot do so for, as a teacher in geography, I find the contents much too restricted for general courses in remote sensing of the environment.

Eric C. Barrett

Eric C. Barrett is Reader in Climatology and Remote Sensing at the University of Bristol, UK.

Global geology

Earth. By F. Press and R. Siever. Second edition. Pp. 649. (Freeman: San Francisco and Reading, 1978.) Hardback \$16.95, £9.90, paperback (Europe and Africa only) £7.20.

This is an excellent book which is specifically designed as a teaching text, but could equally well be read without supervision. It is intended for students with no previous science background and who may not necessarily be intending to follow a geological career—though this text may well encourage them to do so. The reader is not treated as an imbecile, but is assumed to be a reasonable, intelligent being to be treated as an equal. The care that must have been taken in the wording does not show and, while American in spelling, the language is the best form of English-American.

It is arranged in three basic sections: (1) the Earth as an evolving planet and how it is studied, (2) surface processes and (3) internal processes and their surface effects. The individual chapters are planned to be read in any order, which could be dangerous as such a versatility means that repetitions are inevitable. In this case, however, the repetitions are extremely well done, usually comprising a review from a slightly different angle from the way in which the original version was presented.

Each chapter has its own brief introduction and summary, together with a few exercises and a bibliography. The summaries are too brief to act as 'crib-sheets', but the exercises show a healthy versatility, sometimes requiring calculations to be made but usually calling for a real assessment of some particular problem—unlike exercises in some books that merely require the student to find the appropriate section for regurgitation without further thought.

Some difficulties could arise if the student is not following the actual order of the chapters as occasionally relevant information has appeared in previous chapters. Specific sections within a

chapter are boxed off for more detailed consideration, usually at a slightly higher level than the main text, and it is a pity that the bibliography is not similarly indicated as being at a complementary or more advanced level.

The reviewer's standby of printer's errors appear to be absent and the whole volume is very well produced, usually with two text columns per page (25½ × 21 cm) with a wide margin often utilised for figure legends. The illustrations are well chosen, though almost entirely North American, and plentiful, both in terms of photographs and two-tone diagrams—the brown tone allowing attention to be brought to the more salient points. There is a good glossary and index, which will be essential for the new student or for later reference.

The only minor murmurs must be in the coverage of palaeontology in general and of sedimentary structures. In both cases, discussion of the use of fossils for stratigraphical purposes is surprisingly inadequate for any potential geology student. Detailed consideration of the evolution of a trilobite's eye can well be assigned to postgraduate studies, but the real value of fossils, in numerous ways, must be incorporated into a student's thinking at a very early stage. This also gives rise to some uncertainty about the author's use of stratigraphical time periods, certainly within the more advanced 'boxes', when the stratigraphical table only appears as a small diagram within the text, rather than an appendix, and the periods are not defined in the glossary. It is also unfortunate that the opportunity was not taken to give SI units in addition to the American metric unit conversion table.

To carp, however, at such a comprehensive text, so ably presented, should not detract from an unreserved recommendation of this book for either the first-year non-scientific undergraduate or layman. It is extremely good value, even if the dollar recovers!

D. H. Tarling

D. H. Tarling is Senior Lecturer in the Department of Geophysics and Planetary Physics at the University of Newcastle upon Tyne, UK.

Zoonoses and the Origins and Ecology of Human Disease

Richard N. T-W-Flennes

March/April 1979, xvi + 196pp., £9.20/\$19.00 0.12.256050.7

Current works on zoonoses tend to be catalogues of diseases which are interchangeable between man and animals. In this book, a new dimension is added to the question of zoonoses by viewing them against their proper background of ecology, and it is suggested that man has acquired a new disease pattern in new ecological conditions. The author argues that many human diseases are 'new' diseases, originally derived from animal sources, but which have become completely adapted to man as the sole host within the past 5,000 years.

Studies in Archaeology series

Analytical Archaeologist

Collected Papers of David L. Clarke

edited by his colleagues

February/March 1979, approx. 560pp., £13.60/\$26.60 0.12.175760.9

David Clarke was one of the leaders of what has been called the 'New Archaeology', and his first book, *Analytical Archaeology*, has been recognised as a seminal work since its publication in 1968. As both a prehistorian and an exponent of methodology in archaeology his influence extended far beyond Cambridge University, where he spent his entire professional career. Apart from his major books which included *Models in Archaeology*, *Beaker Pottery of Great Britain and Ireland* and *Spatial Archaeology*, as well as *Analytical Archaeology*, David Clarke published a number of papers in diverse journals. At the time of his death in 1976 he had begun to assemble a selection of them for collected publication. The present volume includes this selection, in the planned sections, with introductions written by four of his colleagues and friends and a prefatory biographical sketch and bibliography of David Clarke's writings.

Computer Methods in Geology

T. V. Loudon

March/April 1979, approx. 250pp., £15.60/\$32.75 0.12.456950.1

This book is designed to bring computer methods fully within the reach of the professional geologist, without imposing upon him unnecessary algebraic and statistical formulae. In a simple, readable and logical way, it combines up-to-date ideas from such different quarters as statistics, computer programming, systems analysis or mathematical geology, and presents the computer not as mystifying hardware but as a machine for sharing knowledge. The aim is to introduce the geologist to a range of systems concepts and computer techniques which are making a major impact on his science, and to give practical advice on how they can be implemented, and when they should be avoided.

Biochemistry of Insects

edited by Morris Rockstein

July 1978, 656pp., £19.15/\$29.50 0.12.591640.X

This book covers the biochemistry of insects from various aspects, ranging from the functional role of carbohydrates, fats and proteins to chemical genetics, protein synthesis, insect pigments, and the biochemistry of the insect cuticle. Of special note in this first book on this rapidly growing subject since Gilmour's 1961 volume is the coverage of the biologically important, relatively unique biochemical features of this highly diversified group of animals. These are covered under such subjects as chemical control of intraspecific and interspecific behaviour, pheromones and their use in the control of insects, as well as the chemical defence and detoxication mechanisms in insects, and the biochemistry of the toxic action on insects.

NMR and the Periodic Table

edited by Robin K. Harris and Brian E. Mann

February/March 1979, xvi + 460pp., £35.00/\$62.00 0.12.327650.0

NMR spectroscopy has become firmly established as one of the major methods available to the chemist for structure determination and for obtaining physico-chemical information about molecular dynamics. Recent years have seen several major developments of the technique. In particular multinuclear studies are now more feasible and are becoming popular. Consequently, it is an appropriate moment at which to summarise such work, since no overview of this type has yet been produced. This book is a comprehensive survey of NMR studies of all the elements of the Periodic Table for which such information exists. It will serve both as a source of information for the teaching of NMR and also as a reference work for research chemists, be they involved with organic, inorganic, physical, theoretical or biological chemistry.

Study of sedimentary rocks

Principles of Sedimentology. By G. M. Friedman and J. E. Sanders. Pp. 792. (Wiley: Chichester, UK, and New York, 1978.) £15.75.

THERE is no doubt that this book is a major benchmark in the study of sedimentary rocks similar to the publication of Pettijohn's *Sedimentary Rocks* in 1949.

Principles of Sedimentology is divided into six parts of fourteen chapters, five complements, a glossary, a bibliography and a subject index. Part I reviews the scope, evolution, techniques and philosophy of sedimentology. Part II describes sedimentary particles. The text has been divided into two courses, course 1 for innumerate, and course 2 for numerate students. As only six pages are considered too mathematical for many students this seems an unnecessary distinction which will increase the neuroses of innumerate readers. Part III deals with sedimentary processes, including deposition and diagenesis. Part IV is concerned with the classification and nomenclature of sedimentary rocks and Part V describes modern depositional environments and the environmental diagnosis of ancient sedimentary rocks. Part VI relates sedimentology to stratigraphy and includes a useful review of the relationship between sedimentation and plate tectonics and an introduction to wireline logs including the Dipmeter.

The next 90 pages of the book consist of sections titled "Complements" A to E. These are actually a series of chapters describing modern depositional processes and environments, including deltas, tidal flats and turbidites. This seems an odd arrangement, as most of this material logically belongs either in Part III (Sedimentary Processes) or Part V (Modern Sedimentary Environments).

The "Complements" are followed by a 22-page glossary which is totally unnecessary. One of the many good points of this book is that each new term is printed in bold face type followed by a definition in italic face. This arrangement, coupled with the excellent index, renders a glossary superfluous. Many of the terms included seem unnecessary—for example, "upwelling, viscosity, wadi, surface texture, stuffed basin (*sic*), very-shallow-water wave"; and does one really need to know that the bushmen of the Kalahari desert call a valley "omiribi"?

The glossary is followed by a biblio-

graphy which is nearly 200 pages long. In their preface the authors say that, in response to popular demand, they have not followed the custom of quoting authors and dates at appropriate places in the text coupled with full bibliographies at the conclusion of each chapter. Instead, sections of text are punctuated by lists of names and dates, but not paper titles. Thus the reader must refer to the terminal bibliography to discover the titles of recommended books and papers. Each chapter then concludes with a short reading list. Though the bibliography is very comprehensive the selected reading lists are less so. It seems strange that, for example, Allen's *Physical Processes of Sedimentation* and Wilson's *Carbonate Facies in Geologic History* are not suggested for further reading at the appropriate places in the text. The bibliography itself is excellent and includes citations up to 1977. An odd

feature of this is the frequent use of the term "*sic*" at an average rate of once a page throughout the bibliography.

Considered overall, the book is comprehensive, accurate, well written and excellently illustrated. Students' minds will not be overtaxed by monotonous slabs of text. Every page contains an illustration or heading to break the monotony. Wiley are to be congratulated for producing a book of this magnitude for a mere £15.75.

Despite the eccentric arrangement of its material there is no doubt that this book will be invaluable to sedimentologists, students, teachers, and industrial geologists working with sedimentary rocks.

R. C. Selley is Reader in Petroleum Geology at Imperial College, University of London, UK.

Elementary meteorology

Elementary Meteorology: A Course. By The Meteorological Office. Second edition. Pp. 208. (Her Majesty's Stationery Office: London, UK, 1978.) £4.95.

It is probably not too unfair to say that this book was intended for the education of entrants to the Meteorological Office and is being offered for sale to the general public as a bonus. Perhaps it helps to show that the Ministry of Defence is not only concerned with things secret.

Explicitly, the book is aimed at "weather observers with a background of physics equivalent to that of Ordinary level of the General Certificate of Education"; they will indeed find here much of use and interest.

Chapters on temperature, pressure, water vapour and clouds start from basic physical principles and go on to consider in some detail methods of observation and classification. Chapters on precipitation, thunderstorms and optical phenomena are more descriptive of the processes at work, but the chapter on synoptic meteorology owes much to the early origin of the book and concentrates on correct identification and classification. Forecasting, radar and satellite observation are mentioned briefly. It is a pity that the two rather nice satellite pictures were not dated and do not have an accompanying synoptic analysis.

For this observer, with ordinary level physics, wanting to familiarise himself with meteorological practice and jargon, it is good value for money.

Where else can you find Regnault's equation, the precise authoritative distinction between fog, mist and haze, the definition of Ci spi cgen (no kidding—p81) and much else, for less than £5.

Mind, HMSO does manage to produce an incredibly dull combination of typeface and layout that just shrieks 'educational manual', as you open any page. They do not do justice to Pedgley's nice pictures either.

The book is not suitable for the inquisitive, advanced, student who wants to find out what science there is in meteorology—it does not pretend to be and is not an introductory text. There are too many silly mistakes, like saying the pressure "*in pascals*" is given by weight/area, whereas the relationship is true whatever units it is measured in; and *that* is pretty fundamental physics.

It is ludicrously parochial for a general reader, referring, as nearly as it can, only to weather over the British Isles. Office publications and research are similarly oversold. There is a delightful blit in the Introduction that lists "research into the microphysics of clouds" as one of two "great advances in meteorological knowledge since 1938"—few meteorologists would agree with such an extravagant appraisal. It saddens me to see that the exciting new concepts that have been developed by modern science are going to find their way so slowly and capriciously into the meteorological services.

Fuel and its supply

Energy Resources. By J. T. McMullan, R. Morgan and R. B. Murray. (Edward Arnold: London, 1978.) Paperback £3.50.

Four years ago, in 1975, John McMullan, Roger Morgan and Robert Murray of the New University of Ulster at Coleraine completed a 500-page book entitled *Energy Resources and Supply*, which was published a year later by Wiley. It was a book for graduates and advanced undergraduates, one of the better examples of a genre then burgeoning in popularity. Shortly thereafter the three authors wrote a non-specialist version of the book, only about one-third the length, entitled *Energy Resources*. The paperback version of this second book has now been brought out by Edward Arnold, in their Resource and Environmental Sciences Series, aimed at late school and early university readers. The new book begins with a chapter on energy as an issue; there follow chapters on energy conversion, 'power from natural sources', fossil fuels, nuclear power, and 'inefficiencies'. There is also an appendix on units and an odd and idiosyncratic bibliography.

Energy Resources exhibits many of the virtues of its forerunner. It is readable, written with a light touch and generally good at explanations which convey the shape of a mathematical argument while eschewing the mathematics. The authors do now and then adopt a slightly sneering tone, doubtless intended as jocular but not quite coming off. Anyone who presumes to correct the misapprehensions of others would be better advised, in this fast-moving field, to manifest a certain humility. A great deal has happened since the authors first put together the thesis of their earlier book, and even since the text of their second was finalised in 1976. Their viewpoint, while still widely shared, particularly by official planners, has been overtaken by evolving developments, to such an extent that many of their unstated assumptions have since been scrutinised, analysed and found wanting: for instance their uncritical reiteration that the breeder reactor makes it "possible to use all the available uranium" as fuel, or their distinction between 'weapons-grade' plutonium and any other kind (all plutonium is possible bomb material). Chapter 3 on 'energy conservation', says virtually

nothing about the most important stage of energy conversion: that which takes place at the point of end-use of the energy. The book devotes ten pages to nuclear fusion—which does not yet even reliably exist as a controlled phenomenon, much less an energy source—while giving less than two pages to thermal insulation, undoubtedly the energy technology of highest current priority. Recent work, notably the report *A Low-Energy Strategy for the UK*, by Gerald Leach (Science Reviews Ltd and International Institute for Environment and Development: London, £7.50; for review, see *Nature*, 277, 162; 1979) demonstrates the startling potential for improvement in the

end-use energy-conversion infrastructure, to make far more use of both ambient and fuel energy. In retitling the slimline version of their book the authors would have been more accurate to refer neither to 'energy' nor to 'resources' in general, as they deal only with the narrow range categorised as 'fuel' and its 'supply'. As our understanding of the true dimensions of opportunity in energy policy deepens and broadens, 'fuel supply' seems likely to become less and less interesting.

Walt Patterson

Walt Patterson is Energy Consultant to Friends of the Earth (London) Ltd.

Global chemistry

THE consequences of the release of chemicals into the environment, including their chemical pathways and their effects on flora and fauna (including man), have attracted a great deal of attention in recent years, which shows no sign of abating. Much of the concern has followed in the wake of the development of methods of analysis which allow chemicals to be detected in ever smaller concentrations, and it is becoming clear that we live in a most complex chemical soup. Whether this necessarily places us at more risk than our immediate ancestors, however, is not at all certain, although this is one of the questions to which the two books reviewed here address themselves.

R. A. Horne, in *The Chemistry of our Environment* (Wiley: Chichester, UK; £19.40) has set himself a much more ambitious task than J. Lenihan and W. W. Fletcher, in *The Chemical Environment* (Blackie: Glasgow; hardback £8.90, paperback £4.50)—that is, to give an account of the chemistry of the total environment beginning with nothing less than the Solar System. On the whole he succeeds well, and there is a great deal to learn from a study of his book. The writing is as concise as can be expected in a tome of over 800 pages and the text is illustrated by many excellent figures and tables; each chapter also includes an extensive set of references for those with the stamina to explore the subject further.

What spoils the book for me were Horne's not infrequent incursions into polemic, although in his introduction he does warn that he writes both to instil and to provoke. When he does provoke, however, he often also shows the lack of deep understanding which

characterises the instructional parts of his book. Much of the controversial material appears in chapter 12 which deals with "Man's Perturbation of the Biosphere", which includes, in a section entitled "Internal Pollution", an outburst on the evils of drugs, drink and tobacco. Although no-one would suggest that any of these did not present serious dangers to health, I doubt that the present book is the right forum in which to deal with them.

The final section of the book considers whether or not the Earth will survive, at which point Horne finds himself overcome with a sense of futility. Although not convinced that we are all doomed, Horne nevertheless does consider that life on the planet will become very unpleasant indeed, because of man's propensity increasingly to pollute his environment. The pollution he is most concerned with is this context, however, is not chemical but human. Horne believes that the weight of population will finally produce stresses in the environment which are irresistible. This gloomy prophecy seems a long way from the book's original starting point.

The book which Lenihan and Fletcher have edited, in the series *Environment and Man*, is a much slighter work, and although called *The Chemical Environment*, is a highly selective account of some environmental pollutants preceded by an excellent, short survey of the natural cycles of the elements in the environment by Bowen. Those who read Horne's book would do well to use this chapter as their introduction to the subject.

The remaining chapters of this book vary in style and content, but are all interesting and informative and I enjoyed particularly Kipling's elegant chapter on arsenic.

The book does not give anything resembling a complete account of the hazards which chemicals in the environment present to man, nor does it pretend so to do. However, I am surprised that

the editors felt that they could leave cadmium out of their considerations; perhaps they will include it in a future edition.

Both these books contain much that will instruct and interest the student who wishes to know more about the chemistry

of the world in which he lives, and I recommend both to him.

Tony Waldron

Tony Waldron is Senior Lecturer in Occupational Medicine at the London School of Hygiene and Tropical Medicine, London, UK.

Environmental mixed bag

FOUR books on various aspects of the environment, each useful in its own way, are aimed at very different audiences. Sir Alan Cottrell's *Environmental Economics* (Edward Arnold: London; paperback £1.95) is a succinct, readable, but not very exciting, canter through conventional economics as applied to the environment. It contains all that the non-economist needs to know about these in one handy book, but it is a pity he has not covered the 'Materials Balance' approach of Ayres and Kneese, nor the recent work of Pearce, both of whom tackle the aspects of the environment which are not amenable to cost-benefit concepts.

Measuring and Monitoring the Environment (Blackie: Glasgow; hardback £8, paperback £4), by J. Lenihan and W. W. Fletcher, is the best and most interesting of the series *Environment and Man*, but like the others seems aimed simultaneously at diverse audiences, not all of which are equally well-served. In view of the detailed descriptions of methods for chemical analysis of water, and for analysis of hair, it is a pity that some account of biotic indices, as devised by Woodiwiss, Cairns, Chandler, Cowell and others and recently surveyed by Hellawell were not included as an additional chapter. It is a useful source of references for advanced level students and interested lay-readers and for others seeking an introduction to how the environment is monitored and by whom.

A *Dictionary of the Natural Environment* (Edward Arnold: London; hardback £8.95, paperback £2.95), by E. J. Monkhouse and J. Small, is attractive and easy to use, but is heavily oriented towards geographical aspects of environment. For example, 'species' occurs in connection with clouds, but not with organisms! 'Speciation' is not listed, nor are 'biocides';

and 'biomass' should not really be defined as 'an amount of energy'. These are, however, quibbles, and the book will be useful for ordinary and advanced level students and interested lay-readers. Professionals might find it frustrating.

Richard Fiennes' *The Environment of Man* (Croom Helm: London; £6.95) is more serious, and more ambitious than the others. It ranges over all the man-environment issues which have surfaced in recent years: nutrition and food resources; diseases of affluence; stress; genetics and inheritance; and carci-

nogens. For this it is a convenient point of departure for discussion and investigation. Like all such ventures, however, it has been overtaken by time. For instance, widespread undernourishment is no longer attributable to failure of food production to increase as fast as population; and protein deficiency *per se* is no longer identified as the cause of kwashiorkor and marasmus, nor animal protein as of necessarily better quality than a vegetarian diet. Some controversial claims, such as deterioration of the human race when most infants survive to adulthood, and that man is a product of adversity, as though other species were not, are made as though they have wide acceptance. With these reservations the book is interesting and stimulating.

Pauline K. Marstrand

Pauline K. Marstrand is a Senior Fellow at the Science Policy Research Unit, University of Sussex, Brighton, UK.

Shaping the Earth's surface

The Earth's Changing Surface. By M. J. Bradshaw, A. J. Abbott and A. P. Gelsthorpe. Pp. 336. (Hodder and Stoughton: London, 1978.) £5.95.

THIS is in many ways a remarkable book. The authors have undertaken the daunting task of examining the processes that shape the Earth's surface while at the same time stressing the complexity of landforms in terms of form and evolution. As a consequence the range of coverage is immense, extending from plate tectonics to meteorite impact structures (including a brief discussion of lunar surface morphological development) and from surface geomorphological processes by way of anthropogeomorphology to applied geomorphology. In fact almost every topic of relevance to the study of the Earth's surface is touched upon. Much of this information is conveyed visually, there being no less than 215 plates (many of which are in colour) and a similar number of line drawings, mostly taken from recent publications. The approach is thus refreshing and visually attractive.

However, coverage of such a range of topics in 324 pages of text, much of which is taken up with illustrative material, means that depth of analysis has had to be sacrificed. The text is often disappointing, reference-free and

full of generalities and in places seems merely to be providing continuity between the figures. There are, as must be expected, omissions (for example, no mention of the periglacial hypothesis of tor formation or dilatation jointing) and minor errors; and the use of 'boxed sections' for the examination of 'side issues' or 'background information' (for example, continental drift) may be found distasteful by certain readers. The bibliography is also rather disappointing and lacking in structure, being essentially a list of the more readily available geomorphological textbooks.

In spite of these criticisms this book clearly represents a reasonably priced, well presented and welcome addition to the recently much expanded literature about the Earth's surface. It is to be highly recommended to the interested non-specialist as an informative introduction to the subject. It will also certainly find its way into most school libraries and will provide a definite stimulus to both advanced school students and teachers. Its potential value to the university student and specialist is more difficult to define. There is almost certainly something here for everyone, for it provides pleasant browsing, but in itself it lacks sufficient depth for the average first-year undergraduate and must, therefore, be envisaged as a springboard to more advanced and specialised texts.

David K. C. Jones

David K. C. Jones is Lecturer in Physical Geography at the London School of Economics, London, UK.

● The UK edition of *Soviet Science*, by Zhores A. Medvedev, will be published in April by Oxford University Press. For review, see *Nature*, 276, 146; 1978.

● This year's Spring Books supplement will be published on 26 April.

Physical geology

Holmes' Principles of Physical Geology (Nelson: Sunbury-on-Thames, UK; hardback £14.95, paperback £8.50) is one of the classics of geological education and, now in its third edition, has been used by generations of advanced school students and undergraduates. The new edition is substantially the same as its predecessor, though the revolution in plate tectonics has caused it to have its final chapters reorganised and rewritten. There have also been modifications to the sections on batholiths, granite, granitization, ring dykes and migmatites. Some of the figures and plates have been changed. This does tend to highlight the antiquity of some of the material left over from earlier editions, for the years have not treated some of the illustrations kindly. Overall, however, the volume seems to be quite handsome without going in for some of the more flamboyant touches of its American competitors. The references have been updated for this edition though this is more evident in some chapters than in others.

It is not entirely evident that anyone who owns the second edition needs to go out for the third, for there are some major fields in which important recent developments are not reported. The geomorphologist, for example, will find that descriptive and evolutionary (cyclic) geomorphology predominates, whereas the student interested in the Pleistocene will find many discredited ideas (for example, glacial = pluvial) but far too little on ancient ergs or the deep-sea core record. The desert geomorphologist will find that siefs and barchans are still the basic framework for a study of desert dunes and that salt weathering is not considered.

In sum *Holmes' Principles* is now rather like an old sports coat. It is comfortable and familiar, has been patched up rather obviously, and is not such a good fit as it was, but the basic material is still good for a few more years. At £8.50 for 730 big pages the paperback remains something of a bargain.

Introduction to Geology: Physical and Historical (Prentice-Hall: Englewood Cliffs, New Jersey) by W. L. Stokes, S. Judson and M. D. Picard is also a new edition rather than a totally new book. It very much follows the standard format of basic college texts in physical geology and seems to be neither greatly better nor greatly worse than some of its competitors which I reviewed in *Nature* (266, page 100) this time last year. It has been updated by the addition of the usual material that is put into such new additions: something on plate tectonics, something on space, and something on hazards, environment, energy and resources.

The book covers a great deal of

ground in no great detail and by means of relentless subsectioning. The geomorphologist will find some of the geomorphology irritating: rock weathering rates are largely discussed with reference to grave stones, karst landscapes seem to consist of stalagmites, stalactites and water witches, there is virtually nothing on the Pleistocene sequence determined from ocean cores, and there is very little on modern process geomorphology. This is, however, not of course a textbook for geomorphologists but it is disturbing how poor the geomorphic content is. Overall, however, this book is adequate but a little lacking in character.

Students wishing to gain basic instruction in the geomorphological component of this book would do better to go to B. W. Sparks' *Geomorphology*; R. J. Small's *The Study of Landforms*; A. L. Bloom's *Late Cainozoic Landforms*; R. J. Rice's *Fundamentals of Geomorphology*; or A. F. Pitty's *Introduction to Geomorphology*.

The third volume in physical geology to be considered is the third edition of *Putnam's Geology* (revised by P. W. Birkeland and E. E. Lawson; Oxford University Press: Oxford; £12.25). This book proceeds in a logical way "from a discussion of the materials that make

up the visible earth to the various processes responsible for wearing down and shaping the landscape, concluding with a panorama of earthquakes, mountain building and plate tectonics—in general, the processes that continue to elevate portions of the Earth's Crust".

Of the three volumes this is the one that I liked best. The structure is logical; the illustrative material (including colour plates) is original, simple, clear and striking; there is some attempt at highlighting major concepts and important scientists; and the geomorphological component of the book shows signs of being written by somebody who knows about geomorphology.

By way of conclusion, all three volumes will to varying degrees be acceptable for good advanced school students in geography and geology and they will satisfy some first-year undergraduates in these subjects. Course texts, such as these, are not perhaps used as widely in British Universities as they are elsewhere, presumably because such books have to cover too much in too short a span.

Andrew Goudie

Andrew Goudie is Lecturer in Geography at the University of Oxford, UK.

Metamorphic petrology

Petrology of the Metamorphic Rocks. By Roger Mason. Pp. 254. (George Allen and Unwin; 1978). Hardback £10.95; paperback £5.95.

This book is Volume 3 of the *Textbook of Petrology*, which already includes *Petrology of the Igneous Rocks* (Hatch, Wells and Wells) and *Petrology of the Sedimentary Rocks* (Greensmith). It is a most welcome addition to this set and is aimed at about the level of the second-year undergraduate in a three-year geology course. Dr Mason's objectives are fairly modest and largely concerned with a description of what metamorphic rocks are like. For the most part this approach is very successful, aided considerably by the author's evident desire to be understood. The language used is concise but simple, and definitions are given careful attention. A particularly good feature of much of the descriptive writing is the constant supply of useful tips concerning the actual identification and distinguishing features of minerals under the microscope. From the above it should be clear that the affinities of this book lie more with Harker's *Metamorphism* than with more theoretical works, though it is less comprehensive in terms of rock types covered.

Part I of the book consists of three chapters dealing with definitions, meta-

morphism in general, field relations, structures and fabrics. The bulk of the descriptive work is in the nine chapters of Part II. Here some dozen areas are covered in detail to illustrate various types of metamorphism. Contact metamorphic rocks are illustrated by the Skiddaw, Comrie, and Beinn an Dubhaich aureoles, dynamic metamorphic rocks by, amongst others, the Lochseiten Mylonite, lunar breccias and the Ries crater. Regional metamorphic rocks of Precambrian shields are represented by the Lewisian, and metamorphism in Phanerozoic belts is illustrated by the descriptions of the Sulitjelma and Galway regions and by parts of the Alps (for example, blueschists). Most of the above sections are excellently done and form the most useful part of the book. Much of it is highly readable and the author's personal experience of and interest in the rocks comes through. Two short chapters respectively on ocean floor and upper mantle rocks seem less satisfactory, though credit is due for including these topics at all. This central descriptive section of the book will probably make it very popular, for apart from Harker there is no comparable source of good, meaty descriptive writing on metamorphic rocks (the section in the new *Petrology for Students* by Nockolds *et al* (Cambridge University Press: Cambridge, 1978; hardback £17.50, paperback £6.50) is similar in level but substantially shorter).

New textbooks from Springer-Verlag

An integrated introduction to the neurosciences:

Fundamentals of Neurophysiology

Edited by Robert F. Schmidt
With contributions by J. Dudel, W. Janig, R.F. Schmidt
and M. Zimmermann
Translated by M.A. Biderman-Thorson
Springer Study Edition
2nd revised and enlarged edition 1978. 137 figures.
IX, 339 pages. DM 29,-; US \$ 16 00
ISBN 3-540-08188-7

Fundamentals of Sensory Physiology

Edited by Robert F. Schmidt
With contributions by H. Altner, J. Dudel, O.J. Grusser,
U. Grusser-Cornehl, R. Klinke, R.F. Schmidt and
M. Zimmermann
Translated by M.A. Biderman-Thorson
Springer Study Edition
1978. 138 figures, 5 tables IX, 286 pages
DM 33,60, US \$ 18.50
ISBN 3-540-08801-6

These companion volumes present an integrated introduction to the neurosciences, accessible to students with only minimal background in the life sciences. The emphasis in both books is on clarity and each term is defined and explained as it is introduced in the text. Superior illustrations and suggested readings permit the student to easily grasp the subject. These books are of interest to everyone who wishes to, or must, delve into the potentialities and limitations of human sensory experience.

R. NIEUWENHUIJS, J. VOOGD, C. van HUIJZEN

The Human Central Nervous System

A Synopsis and Atlas
1978. 154 figures. IV, 253
pages. DM 48,-; US \$ 26 40
ISBN 3-540-08903-9

Contents: Introduction —
Gross Anatomy. — Brain

Slices. — Microscopical Sections — Functional Systems.
This atlas provides a comprehensive pictorial survey of the macroscopic and microscopic structure of the human central nervous system. The pictorial material encompasses 154 half-tone and line drawings, which are all derived from original macroscopic and microscopic preparations. Considerable thought has been given in the preparation of these drawings to an optimal combination of clarity and exactness.

E. SCHOLTYSECK

Fine Structure of Parasitic Protozoa

An Atlas of Micrographs, Drawings and Diagrams

1979. 186 figures. VIII, 206
pages. DM 80,-; US \$ 44 00
ISBN 3-540-09010-X

This atlas utilizes a new method of analyzing electron micrographs allowing a more definitive characterization of protozoan fine structural organization. An electron micrograph and an analytic drawing are arranged, along with a descriptive text on pages facing each other to facilitate comparison. The atlas is designed for students, instructors, and researchers in the fields of protozoology, parasitology, veterinary or human medicine, and makes a valuable tool in the study of fine structure in general.

A. F. WILLIAMS

A Theoretical Approach to Inorganic Chemistry

1979. 144 figures, 17 tables. Approx. 330 pages
Cloth DM 98,-; US \$ 53 90
ISBN 3-540-09073-8

The considerable strides made in inorganic chemistry in recent years necessitate the establishment of a theoretical framework if the student is to acquire a sound knowledge of the subject. This book outlines the application of simple quantum mechanics to the study of inorganic chemistry, and shows its potential for systematizing and understanding the structure, physical properties, and reactivities of inorganic compounds.

Prices are subject to change without notice

H.B. GRIFFITHS, P.J. HILTON

A Comprehensive Textbook of Classical Mathematics

A Contemporary Interpretation
1978. 94 figures. XXIX, 637
pages. DM 44,-; US \$ 24 20
ISBN 3-540-90342-9

This textbook conveys the spirit of contemporary mathematics at the undergraduate level. It has been written with prospective mathematicians, computer scientists, and engineers in mind and especially for future teachers. Apart from its suitability for use in the classroom, the book makes an exhaustive reference and lends itself well to independent study.

THE VITAL LINK BETWEEN SCIENCE AND INDUSTRY..... **ENDEAVOUR**

**A Review of the Progress of Science and
Technology in the Service of Mankind**

Editor: **TREVOR I. WILLIAMS**, *Oxford*.

ENDEAVOUR is the vital link between scientific discovery and the application of new knowledge to industry, agriculture and medicine.

In three decades of publication, it has become one of the world's leading and most authoritative reviews of scientific and technological progress. Articles have been commissioned from all quarters of the globe and over 30 Nobel Laureates are included in the distinguished list of contributors.

Recognising the importance to mankind of the continual cross-fertilization of new scientific ideas with current industrial and commercial attitudes, ENDEAVOUR concentrates on topics that are equally relevant to both sides.

Its emphasis is primarily on subjects of global, social, political and economic consequence. Pollution, alternative energy developments, new scientific discoveries and the most significant biological and biochemical issues are covered.

Nobody with an interest in the implications of scientific progress for world development should be without ENDEAVOUR.

IHG2B

The book also has chapters on metamorphic reactions (including a discussion of facies), isotope geology, the use of the electron-probe, and a final chapter on metamorphic rocks and the evolution of the Earth. The theoretical sections are on the whole somewhat condensed and the reader will probably only acquire a superficial familiarity with the topics discussed. For example, in the section on isotopes there is no mention of the fundamental equation of radioactive decay and its derivatives as used in isochron diagrams. Similarly, in discussing metamorphic reactions thermodynamics is more or less avoided. These are both cases where more detail would have enabled problems and exercises to be inserted, probably with a considerable benefit to the understanding gained by the reader.

In summary, the book is rather

disappointing on the topic of metamorphism itself: it is not particularly stimulating, at least partly because it gives very little coverage to some of the fundamental problems of metamorphism such as where the heat comes from and how the study of metamorphism is applied to the understanding of tectonic processes. On the other hand the accounts of metamorphic rocks are rather well done, and the book is worth it for these parts alone. One sympathises with the desire to keep the text short (and cheap) and it may perhaps be impossible to cover all aspects of the subject satisfactorily in a work of this length. None-the-less this book should provide useful background reading for most courses in metamorphic petrology. **K. G. Cox**

K. G. Cox is Lecturer in Petrology at the University of Oxford, UK.

Three branches of petrology

Petrology for Students. By S. R. Nockolds, R. W. O'B. Knox and G. A. Chinner. Pp. 435. (Cambridge University Press: Cambridge, 1978.) Hardback £17.50; paperback £6.50.

ALTHOUGH Harker's *Petrology for Students* is discontinued after more than 80 years, this book with the same title and from the same stable is obviously its natural successor. It now has three authors, one for each of the main divisions of petrology. With its emphasis on the description of rock thin sections under the microscope it is very much in the Harkerian mould. This impression is reinforced by the use of many of Harker's original 'microdrawings'. From the amount of detailed information presented, the book seems to be most suitable for the second year of a conventional three-year geology course, but as the three branches of petrology are usually taught separately at this level, its success depends on a consistent approach and level of achievement.

The section on igneous rocks (approximately half the book) provides a thorough and systematic account of the petrography of the main igneous rock groups, with useful supporting information on the major element chemistry. The introductory chapter on textures would be more effective if it was illustrated *in situ* (rather than referring to the appropriate figures in later chapters), and the chapter on classification is disappointingly brief and makes no concession to other schemes or to recent attempts to

standardise nomenclature. A more serious drawback is the persistent emphasis on specific examples, many of which come from obscure localities and represent material the average student is unlikely to meet in the flesh. This whole section has a distinctly old-fashioned flavour; the collection of facts is carefully curated, but the presentation is lifeless.

The treatment of sedimentary and metamorphic rocks is generally more effective in that it manages to combine the systematic petrography with some discussion of the rock-forming processes. The sedimentary section contains a useful introductory chapter on textures, followed by a logical and up-to-date treatment of the main groups of terrigenous and chemical sediments. The metamorphic section is less conventional in that a chapter on textures is followed by discussions of metasomatism and melting, facies classification, regional metamorphism, granulites and eclogites, blueschists, and low-grade metamorphism.

This book is quite good value in terms of the quantity of information provided, but it is not altogether successful as a coherent treatment of the three branches of petrology. It would seem more sensible to invest in separate books on igneous, sedimentary and metamorphic rocks, as these generally provide a more complete picture, combining the descriptive material with a discussion of processes and geological context. Without these petrography can be extremely arid.

Organic chemistry

IN this section last year, four fat American textbooks were reviewed. This year there are two slim Americans, together with three British books (one large one): two new editions of established works, and a new book written by last year's reviewer, Stuart Warren.

Both of the American texts attempt to cover the main themes of modern organic chemistry, with some mention of biological chemistry, in about 500 pages. One of them, *The Essence of Organic Chemistry*, by J. M. Cram and D. J. Cram (Addison-Wesley: Reading, Massachusetts, and London) succeeds quite well in this endeavour; but the other, *Organic Chemistry: A Brief Survey*, by R. L. Baumgarten (Ronald: New York, £10.25, \$18.45) is rather disappointing. The first six chapters of Baumgarten cover the fundamentals (bonding, nomenclature, and so on), then the middle portion of the book is devoted to the chemistry of the various classes of organic compounds. Finally, more specialised topics are dealt with in eight chapters: these include stereoisomerism, synthetic polymers, primary and secondary metabolites and an overview of spectroscopy. There are an enormous number of problems, but only selected answers are given; and although there are some interesting half-tone illustrations, only rare attempts are made to represent realistic three dimensional structures of molecules. The chemistry throughout is fairly basic, and given the intended readership—students majoring in biology, home economics, nursing, and so on—this is probably all right; but the big disappointment is the lack of emphasis of the relevance of organic chemistry to the Life Sciences. Surely these students should know something about prostaglandins, insect pheromones, and biologically active peptides, to name but a few omissions.

In contrast, the relationships between organic chemistry and biochemistry are nicely handled in Cram and Cram. The first four chapters introduce bonding and structure, etc., through a discussion of hydrocarbon chemistry, and this sets the scene for subsequent coverage of the various classes of organic compounds. Mechanistic considerations are slotted in where relevant, and the illustrative examples are well chosen: the involvement of substitution reactions in terpene biosynthesis; a discussion of the Claisen ester condensation leads on to the reactions of acetyl-thioenzyme A; and many others

The final four chapters deal with aromatic chemistry, the formation of carbon-carbon bonds, carbohydrates and nucleic acids, and spectroscopy. One glaring omission from this last section is mass spectrometry—in fact, both books are rather weak on spectroscopic methods. Throughout the book discussion of fundamental chemistry is a prelude to coverage of applications to biochemistry. For example, after basic stereoisomerism we have the dynamic stereochemistry inherent in enzyme structure and catalysis, and a section on epoxides includes mention of the sex pheromone of the gypsy moth (an epoxide), and of 2,3-epoxy-squalene as progenitor of the steroids. At the end of each chapter there are summaries of reactions, new terms and topics, and also many useful problems (others are interspersed throughout the chapters) for which answers are supplied. The illustrations are good and include realistic structures for complex molecules.

In summary, although neither book is suitable for degree courses in chemistry, Cram and Cram can be recommended for service courses in chemistry for students of biochemistry, medicinal chemistry, and so on.

The large British book under review is Vogel's *Textbook of Practical Organic Chemistry* (fourth edition revised by B. S. Furniss, A. J. Hannaford, V. Rogers, P. W. G. Smith, and A. R. Tatchell, Longman: London and New York; £17.50). Twenty-two years have elapsed since the previous edition of this book was published, and many new experimental techniques have appeared in this period. This is reflected in the changed emphasis of the present edition. Thus, chromatography increases from seven to thirty-eight pages; and there is a big new section on the interpretation of spectra: infrared and NMR spectra are particularly well covered, and the coverage of mass spectrometry is fair. At the end of the book there are additional correlation tables for IR, NMR and mass spectra (as well as sections on solution characteristics, hazards, and first aid). The bulk of the book comprises a total of 460 primary experiments with many additional cognate preparations, for which full experimental details are given. This is followed by a chapter on qualitative organic analysis, which includes the discussion of spectroscopic techniques as well as all of the classical methods. There are many new experiments, which include: the use of sulphur ylides (one experiment), allene formation (2), cuprates (1), enzymic resolution (1), phase transfer catalysis (1), hydroboration (2), and so on. However, there are several omissions: no

examples of the Baeyer-Villiger oxidation, or the Simmons-Smith reaction, and no mention of the use of alkane dithiols and other reagents which can bring about a reversal of polarity of functional groups (*umpolung*). Perhaps most disturbing is the dearth of Wittig reactions—only one phosphorus ylid is prepared and used—yet there are 31 experiments involving Grignard reagents—surely this excess does not reflect the respective utilities of the two types of reagent. One other disappointment is the total absence of NMR or IR data from the experimental section. Had the chapter on spectroscopy been introduced earlier in the book, and data supplied for each of the compounds synthesised, this book would have been enormously enriched. As it stands the reaction products are characterised by melting and boiling points which, though useful, hardly reflects the modern reliance on spectroscopic proof of structure. The authors state that the book is a one-volume reference text for undergraduates and postgraduates, and with certain reservations this is true, though at £17.25 I doubt whether many individuals will buy it. Certainly all research laboratories should possess a copy, but the people who will find it most useful are those who must devise experiments for chemistry courses.

The remaining books—*Some Modern Methods of Organic Synthesis* (second edition, by W. Carruthers; Cambridge University Press: Cambridge; hardback £25, paperback £7.95); and *Designing Organic Syntheses: A Programmed Introduction to the Synthon Approach* (by S. Warren; Wiley: Chichester, UK, and New York; paperback £3.95)—cover the methodology of synthetic organic chemistry. They are complementary, as the former deals with synthetic methods, whereas the latter shows the reader how to analyse a synthetic problem, and choose the most expeditious synthetic route.

The first edition of Carruthers appeared in 1971, and this new edition has increased in size by about 130 pages. Much of this expansion is due to new sections on organo-sulphur, -selenium, and -silicon chemistry, *umpolung*, and the selective alkylation of ketones, but there are also about twice as many references and a larger index. The basic format remains the same with chapters one and two on the formation of carbon-carbon single bonds and carbon-carbon double bonds. There are much enlarged sections on α -thiocarbanions, and the Wittig reaction, which now includes useful and timely information about sulphur ylides; and new sections on *umpolung* and cuprates. Chapter three covers the Diels-

Alder reaction and includes a new section on the intramolecular version of this reaction, with extended coverage of catalysis by Lewis acids, and of the ene reaction. It also has a new section on the utility of allyl cations, but this is too short, and rather out of date to be of much use. Of the remaining four chapters, the one on organoboranes and organosilanes is particularly good. There are a few disappointments, such as the poor coverage of phase transfer catalysts and crown ethers, and the fact that none of the references are post-1976, and most are pre-1974. Otherwise, the book provides a very good introduction to the methodology of organic synthesis, and should be essential reading for advanced undergraduate courses, and for all postgraduates and others actively involved in organic synthesis.

Stuart Warren's book is a programmed introduction to the design of organic syntheses. It has all of the advantages of a programmed text in that problems are set, and then solved once the reader has had chance to attempt a solution; and the choice of problems is very good. This book represents the first serious attempt to teach undergraduates how to disconnect a target molecule, to provide fragments (synthons) for which syntheses may be discerned. Stephen Turner's book, *The Design of Organic Syntheses* (Elsevier, 1976) is pitched at a much higher level. One particularly appealing feature of the book is the way in which the analysis of many simple target molecules is tackled before the

same methods are applied to complex targets. It is often forgotten that undergraduates are primarily taught synthetic methods, and it is strange at first to think in a retro-synthetic sense. Initially, Stuart Warren takes the reader through the various types of disconnections: one-group, two-group, and illogical (that is, ones where a functional group interchange must be applied before the disconnection can be made). He then passes on to more complex disconnections, such as those involving 'retro-Diels-Alder' reactions, and those involving heteroatoms or small rings; and finally discusses strategy at some length. In fact this section could almost stand by itself as a sort of guide to 'gamesmanship' in organic synthesis. Throughout the book there are review problems, many difficult, which will be of particular utility for lecturers as a source of set work; and most problems have a key literature reference supplied. Any person working through this book will gain a fundamental and very useful understanding of 'synthetic analysis', and it should be essential reading for anyone involved in organic synthesis. My only small reservation is that it might be too difficult for undergraduates, except those taking advanced courses, although their understanding of organic chemistry will be much improved if they can work through it. And at £3.95 it has to be the bargain of the year

John Mann

John Mann is Lecturer in the Department of Chemistry at the University of Reading, UK.

Communicating chemistry

THE large void which separates scientists from non-scientists is initially due to the language barrier. Each particular branch of science has its own linguistic pattern, and communication between practitioners in each branch is often completely incomprehensible to non-scientists. Thus, it behoves the scientist who wishes to communicate with the non-scientist to teach the basic language thoroughly. It is well to recall that we all begin as non-scientists and it is undoubtedly true that many great minds have been lost to scientific endeavour because initial interest was destroyed by a failure of the teacher to lay down a basic framework for the subject. Conversely there are numerous working scientists whose enthusiasm for their subject was nurtured by excellent teachers who could not only teach well but also transmit their own love for, and excitement derived from, their

particular area. (Also, one must admit that many of us can recall teachers who clearly did not understand the principles they were employed to transmit to us.)

Because of the nature and requirements of US degree courses there are several hundred thousand students taking general chemistry courses every year, and probably the majority of these do not intend to eventually major in a science subject. The market for general chemistry textbooks is very large and the competition amongst authors is very keen. This has resulted in some excellent texts being published in the past five or so years. The requirements are often severe, for example, teaching thermodynamics to large mixed-ability classes, but many authors have managed to simplify quite esoteric chemical and physical concepts without loss of integrity, usually with the aid of excellent diagrams and artwork. Thus, a good general chemistry book can often represent the firm basis of an undergraduate's chemical knowledge. At the other end of the

Appleton books for the medical student:

BASIC SURGERY: A SYMPTOM-ORIENTED APPROACH Bernard Gardner et al

In 600 pages four distinguished U.S. surgeons prepare the student to evaluate and manage the commonest surgical complaints, as they draw on their own clinical experience in a thoughtful presentation of patho-physiology, treatment, repair and recovery. Future practitioners and specialists will find Basic Surgery a model of coherence.

1979 627pp Pa. £13.70

THE HISTORY AND PHYSICAL EXAMINATION Howard P. Lewis

A practical guidebook for the medical student which makes history-taking and physical examinations easy to comprehend and master. It begins with a systematic procedure for obtaining the patient's history, which is paralleled by a photographically illustrated summary of the physical examination. Designed to help students think clinically and construct a differential diagnosis. Dr. Lewis's concise text will promote improved competence.

1979 160pp Pa. £5.80

CUTTING'S HANDBOOK OF PHARMACOLOGY Sixth Edition T. Z. Csaky

In a major revision since the 1972 edition, Cutting's Handbook under its new editorship offers readers a fingertip reference to every important drug in current use. Organised in broad pharmacologic or therapeutic groups, each chemical agent is highlighted for these salient features: history, chemistry, mechanisms, toxicity, dose and use. Structural formulae are given so that molecular similarities can be easily compared.

scale one finds, however, texts which contain little chemistry but much repetition. The best texts I have come across are those written by active researchers, for example, by L. Pauling, H. B. Gray, D. H. Busch; the worst are almost invariably written by 'chemical educationalists'.

The texts reviewed here represent a fair cross-section of the available books, although none are as good as the very best available. The second edition of Fine's *Chemistry* (Williams and Wilkins: Baltimore; \$16.50) admirably exemplifies the wide scope frequently offered.

Fine's book is the most attractive of the present collection, but having said that I shall use it to illustrate some of the inconsistencies which appear in it and some others reviewed here. For example, in a book which includes two chapters on quantum principles and discusses the Schrödinger wave equation why is it necessary to include a section in chapter 1 entitled "Using Powers of Ten" and includes the mind-stretching equation $1.5/10^4 = 1.5 \times 10^{-4}$. Furthermore, a feature of many of these books is contained here, inasmuch as in a book of almost 800 pages only one chapter (37 pages) is given over to organic chemistry. Also, many of the vignettes in the margins of the pages seem to have little to do with text generally and I think are unnecessary. Unlike most of these books Fine's book contains some bad art-work, e.g. the structures drawn on pages 738 and 743.

I enjoyed, too, perusing *Chemistry: A Modern Introduction* (W. B. Saunders, Philadelphia and London; £12) by Brescia *et al.* and similarly admire the wide scope, but am again dismayed to find that nuclear chemistry and organic chemistry warrant approximately equal treatment in terms of pages devoted to them. I was surprised to find in the first two paragraphs of the preface the statements: "This book is written for highly motivated students . . . the work is therefore, in part, intentionally repetitious and written in a language to stimulate students and help maintain their enthusiasm." Repetition will never appeal to the highly motivated student. Again, I suspect that the highly motivated student will wonder why Figure 1.3, which contains an illustration of a rule marked in inches alongside one marked in centimetres, is necessary.

I would find it difficult to recommend E. I. Peters' *Introduction to Chemical Principles* (W. B. Saunders: Philadelphia and London; £10.50). More than the previous two books I find it difficult to know at whom the book is aimed: at those students who can appreciate the quantum mechanical model of the atom (p70) or those

who need to be taught how to count to significant figures or to be told that meter sticks are calibrated in millimetres (p45).

W. L. Masterson and E. J. Slowinski's *Chemical Principles in Qualitative Analysis* (Holt-Saunders: Philadelphia and London; £10.50) is a "student-oriented book", but I can quite truthfully say that I have not in the past ten years come across a book which would in my opinion deaden any interest in chemistry a student had before being unfortunate enough to have to use this book. The fault essentially lies not in the chemistry, but in the attempts to introduce old-style wet methods of qualitative analyses wherever possible, quite apart from the large section of the book (153 pages) devoted to qualitative analysis of cations and anions. Despite the revolution which has occurred in analytical procedures during the past 15 years I am prepared to admit that wet-method qualitative analysis deserves some, essentially historic, treatment in modern books. But I find it depressing that this book makes no mention of NMR or atomic absorption spectroscopy (and little mention of mass spectroscopy), and even more depressing to think that there are Colleges in the US which must still be introducing practical

chemistry to Freshmen by way of qualitative analysis.

G. C. Hill and J. S. Holman's *Chemistry in Context* (Nelson: Sunbury-on-Thames, UK; £5.95) is aimed at students studying chemistry to advanced level lab school, and one can clearly see the influence of American style in the presentation. One might roughly equate the attainment of College Freshmen students in the US with advanced level students in the UK, and thus it is interesting to note that this book devotes 142 out of 518 pages to organic chemistry. I liked this book, but did occasionally find that the peripheries are allowed to intrude on, and confuse occasionally, the serious matter of communicating chemistry. Thus, for example, page 1 includes a picture and a biographical note on John Dalton, a reproduction of Dalton's symbols for the elements, an electron micrograph of copper phthalocyanine, and a short quiz on atoms. Incidentally, the thoughtful student will find their d-orbitals splitting diagram on p272 confusing.

C. A. McAuliffe

C. A. McAuliffe is Senior Lecturer in Chemistry at the University of Manchester Institute of Science and Technology, Manchester, UK, and Adjunct Professor of Chemistry at Auburn University, Alabama.

Physical chemistry conceived

CHEMISTRY is a three-dimensional subject. Those incapable of visualising the shapes of molecules represented by two-dimensional structural formulae have to struggle with the topic. The first introduction to this aspect normally comes with tetrahedral carbon bonds and the topic of stereochemistry remains central, especially in organic and biochemistry. The fact that Kurt Mislow's *Introduction to Stereochemistry* (Benjamin/Cummings: Massachusetts; \$11.50) is now reprinted for the sixth time speaks for itself. It was one of the first undergraduate monographs used to supplement a major text and as such outstandingly successful. Emphasis is placed on structural stereochemistry and reactions are avoided. It has three sections; structure and symmetry; stereoisomerism and the separation of stereoisomers. Although explained, it rightly describes hybridisation as "no more than a convenient mathematical fiction".

In *The Chemical Bond* by J. N.

Murrell, S. F. A. Kettle and J. M. Tedder (Wiley: London and New York; £11, \$23.50) hybridisation again takes a back seat, despite its historical importance in the understanding of three-dimensional shapes. This new book, by the authors of the established *Valence Theory* (Wiley: London and New York) is written from the contemporary standpoint with the evidence of the thousands of published *ab initio* molecular orbital calculations in mind. Valence bond and molecular orbital theories are not presented as equal rivals. The fact is that computational ease has left the molecular orbital approach dominant over the alternative, just as the internal combustion engine eclipsed the steam car, despite theoretical objections. Computational techniques are not included and indeed the book demands minimal mathematical skills. Nonetheless any undergraduate, having read it would be much better able to make the transition to the research literature than one brought up on the traditional diet. The topics are introduced in what is perhaps an unfamiliar order (perturbations in chapter 11 and valence bond theory in chapter 13), but this is amply justified. Strong points are the inclusion in an undergraduate text of good accounts of band theory in solids, reactivities of molecules and of intermolecular forces.

The chemist's chief device for coping with the three-dimensional nature of his subject is to use molecular models, although these have limitations as Mislow points out. The models of the title in *Chemistry through Models* by C. J. Suckling, K. E. Suckling and C. S. Suckling (Cambridge University: Cambridge; £15), are interpreted in a much wider manner than mere mechanical analogies. Theories, hypotheses and laws all fall within the definition of a model, so that, for example, the ideal gas law, $PV=RT$, is in this sense a model. The book is subtitled *Concepts and Applications of Modelling in Chemical Science, Technology and Industry* and it thus attempts the rare feat of bridging academic chemistry and biochemistry and industrial application. It is very original, well written and thought provoking. Early chapters introduce models in the general sense and explain the modelling process. The main body of the text then applies models to the concepts of chemistry; quantum mechanics; molecular orbital and valence bond theories; spectroscopy and structure determination; synthesis and reactivity. A biochemical chapter emphasises enzymes but also considers simulations of the origins of life on Earth. Two final chapters treat the design of a chemical plant and innovation, including some account of economic models. The book is highly recommended both as a fresh look at some familiar topics and as an extension of chemistry beyond a student's normal confines. Modelling is a powerful tool which is prone to misuse especially, physical scientists often feel, in the realms of economics or sociology. Here the authors give clear warnings against unimaginative use and suggest how pitfalls can be avoided, all in a very readable fashion.

Physical Chemistry, by I. N. Levine (McGraw-Hill: New York and London; £21) is a late runner in the valuable stakes to find a successor to Moore's *Physical Chemistry* (Longman: London; Prentice-Hall: Englewood Cliffs, New Jersey), thought by some of the pundits to be ageing and capable of being overtaken. Earlier declared challengers were reviewed in this place twelve months ago (*Nature* 272, 101; 1978.). This new starter for the standard undergraduate course in physical chemistry comes from a successful stable and is in every way a thoroughbred. It is hard to find fault but looking at the field as a whole it is impossible not to choose the rival *Physical Chemistry* by P. W. Atkins (Oxford University Press: Oxford; Freeman: San Francisco) as favourite.

Graham Richards

Graham Richards is Lecturer in the Physical Chemistry Laboratory, University of Oxford, UK.

Biophysical chemistry

THE two books under review arrived in the middle of the usual self-examination that follows marking terminal examinations and it was with some relief that I found that the problem of catching and holding the interest in physicochemical problems of biologically orientated students must be unsolved as yet. The authors of *Biophysical Chemistry: Principles, Techniques and Applications* (A. B. Marshall; Wiley: New York and Chichester, UK; £13.25) and *Physical Chemistry: Principles and Applications in Biological Sciences* (I. Tinoco, K. Sauer and J. C. Wang; Prentice-Hall: Englewood Cliffs, New Jersey; hardback \$19.95, paperback \$6.78) appreciate that in recent times several textbooks have been produced which offer recipes for solving this problem, but they must feel (as I do) that these texts all have deficiencies. My overall view of these two new textbooks is that jointly they seem to have good mixes which go a long way to solving the problem.

The authors of both books obviously appreciate that the first requirement is to teach through examples taken from biochemistry and biology using wherever possible familiar problems which lead easily into the physicochemical concepts of molecular action. The descriptions inevitably lead to mathematical formalism, so both textbooks give appendices which summarise the essential components of the mathematics. In addition to the numerous solved examples in the texts, both books give extensive lists of testing problems at the end of each chapter, and, unlike some earlier textbooks, both give answers to the problems, although this means purchasing an additional volume to Marshall's book.

Despite their apparent overlap in the intended audience, Marshall's book is a more specialised text for students of biochemistry studying the wide range of subjects which are collectively called biophysics, whereas the second covers all aspects of physical chemistry for first-year students and omits a lot of the physics given by Marshall. In view of the differences in content, this review may serve a more useful purpose if their details are discussed separately.

Biophysical Chemistry is well written and uses many clearly explained examples from biology to illustrate the principles. Generally the approach has been to take a simple concept, develop this and use the models as a basis to discuss a range of topics throughout

the section. A good example here is the description of the motion of a weight on a spring as an illustration of the concepts of harmonic motion. These concepts are then used to discuss the underlying principles of absorption and dispersion of light, scattering phenomena and transient phenomena such as jump kinetics. This section is one of a total of six sections which cover the laws of thermodynamics, hydrodynamics, kinetics, quantum and statistical mechanics, and one must admire the extensive coverage given to each division.

It must be inevitable in a book of this wide range that the same symbols would be used in apparently unrelated proofs, but occasionally this does lead to confusion. For example, f is used to describe hydrodynamic friction as well as a damping constant for harmonic motion: although the two could have been related through polarisability of the molecules (which incidentally only receives a passing mention), this would not be apparent to undergraduates. One further minor criticism was the omission of transport numbers in the treatment of gel-electrophoresis. Surely this concept would have simplified the understanding of disc(ontinuous)electrophoresis and isotachophoresis.

My own personal sorrow was to see the passing of names associated with equations and concepts: the relationship between electromagnetic intensity and square of the amplitude is no longer called the Poynting theorem, nor are the names Lorenz-Lorenz associated with the relationship between polarisability and refractive index. It always seems more human to have these associations, although I realise that the modern trend is to reduce these connections.

Physical Chemistry is structured differently from *Biophysical Chemistry* and covers both the classical concepts of physical chemistry as well as giving a good coverage of quantum and statistical mechanics. As expected from authors of their reputation, the treatment of these two forms of mechanics is particularly good and could be recommended for all first-year science students. At the end of each chapter is a useful summary of the important relationships derived in the chapter. This makes it easy for students to cross-reference between chapters during revision. I was sorry to see that the Gibbs adsorption isotherm was not included, as it is an old friend which can form a sound basis for discussing hydrophobic effects: possibly this is a logical omission, as hydrophobicity was not discussed, nor were the properties of aqueous solutions given special mention.

Both books seem to avoid the thorny problem of concentration dependence of parameters. Experience shows that one stumbling block for most astute non-physical undergraduates studying physical chemistry is the apparent inability of its theories to deal with properties of solutions at finite concentrations; simply assigning the deviations to virial coefficients (which are not mentioned in *Physical Chemistry*) is not sufficient. I had hoped that the authors of these books may have found a satis-

enthusiastic, fying simple solution for explaining these important solute-solvent interactions. Despite this small disappointment, I feel I could strongly recommend my students to use these textbooks in the future, but I suspect that the cost of Marshall's will be the greatest barrier to all but the most S. P. Spragg

S. P. Spragg is Lecturer in Physical Chemistry at the University of Birmingham, UK.

Primary and secondary metabolism

PRIMARY metabolites or metabolites that are essential to organisms by providing materials and energy for their maintenance and growth have traditionally been studied by biochemists. *Primary Metabolism: A Mechanistic Approach*, by J. Staunton (Clarendon, Oxford University Press, Oxford; £6.50), takes a chemist's view of the reactions involved in primary metabolic pathways and, as the title suggests, looks at the steps from a mechanistic point of view.

The text commences with an excellent treatment of the main reactions involved in the pathways. The energetics and mechanisms are explained with particular clarity. The role of ATP and other energy-rich phosphates is considered in detail and this is followed by a study of thioesters including coenzyme A derivatives. Subsequent chapters deal with other important cofactors; thiamine pyrophosphate, lipoic acid, nicotinamides and the flavins are introduced and their catalytic roles explained. Current theories on the organisation of the electron transport system are presented in a clear and convincing manner. Here and throughout the book areas under active investigation are indicated.

Having set the scene and described the principal characters, the author describes some of the major metabolic pathways. The catabolism of glucose and its role as an energy source is first described, then photosynthesis and the anabolism of glucose is considered with emphasis on the energetics. The remaining chapters discuss the use of fatty acids as an alternative energy store, transformations of tetrahydrofollic acid derivatives and amino acid metabolism. Mechanisms are discussed for each reaction and the overall strategy and interlocking nature of the pathways are presented in an admirable way that leaves the reader marvelling at the beauty and intricacy of

the transformations.

The book can be confidently recommended to all students of chemistry and biochemistry as a well balanced and refreshing account of primary metabolism. Research workers will also find stimulating ideas for both biological research and organic synthesis within the book.

Secondary metabolites are those metabolites, often called natural products, that seem to be non-essential to the organism. *Secondary Metabolism*, by J. Mann (Clarendon/Oxford University Press, Oxford; £9.75) surveys our current knowledge of the biosynthesis of these metabolites and emphasises the ecological, toxicological and pharmacological properties of the compounds.

The text begins by introducing some aspects of primary metabolism essential to the understanding of secondary metabolism. The second chapter deals with compounds derived from acetate, including prostaglandins and polyketides. Chemical analogies are given for the more important biological reactions emphasising that any theory of biological transformations must be

based on sound mechanistic reasoning. The third chapter dealing with isoprenoids pays particular attention to the stereochemistry of the transformations. Well established results are used for most of the examples and when a pathway or mechanism is not substantiated this is clearly stated.

Aromatic compounds derived from shikimic acid and the alkaloids are discussed in the next two chapters. Metabolites of particular contemporary interest have been chosen to illustrate the biosynthetic pathways. The treatment of the major classes of secondary metabolites is completed with chapter six which concentrates on metabolites of mixed biosynthetic origin. The final chapter gives an enlightening view of the ecological aspects of secondary metabolites and throughout the book the functions of the compounds are stressed to give purpose to the biosynthetic study.

The text is well organised, covers a large area of natural product chemistry suitable for undergraduates and is a valuable introduction for those beginning research in this field. At the end of each chapter there is a small number of problems selected from the recent literature, and the student is referred to the original literature for solutions. The author stresses that it is not a reference text but there is a comprehensive list of such texts in the list of books and reviews suggested for further reading. Overall this is an excellent book and should be very popular.

R. A. HILL

R. A. Hill is Lecturer in Organic Chemistry at the University of Glasgow, UK

Physics applied to biology

BECAUSE of the complexity and number of variables involved in biological phenomena it is difficult to get precise quantitative data on which to base theories of structure, function and organisation. Yet as understanding progresses it is becoming more common to interpret biology in physical terms, and move towards the goal that "all science as it goes to perfection becomes mathematical in form". Physical and mathematical formulation are the inevitable direction in which the biological sciences must develop. There is a growing appreciation of the need to increase the quantitative and mathematical content of courses in the life sciences. To meet this educational requirement a number of books have been published over the past decade at the introductory, intermediate and specialised levels of physics and mathematics applied to biology.

The present text is at the first level, and although it is claimed to be written for degree and diploma students, who only have a knowledge of ordinary level school physics and mathematics, its content is just above that of an advanced level school syllabus. It broadly covers the field given in the first MB syllabus to Medical students, and, like the latter course, attempts to introduce basic physics by graphical methods without the use of calculus. There are a number of good textbooks available in this field and any new addition will as a consequence be subject to very critical appraisal. In curricula content it is well balanced, starting with a chapter on force, motion and energy, followed by chapters on waves, atomic and molecular structure, electricity, light, heat, and finishing with radioactivity and radiobiology. Most of the text is precise, and in respect of descriptive material well presented. It is with the problem of introducing new concepts and conveying an understanding of the principles of physics that the book

is weak. Particular areas that need revision are the meagre introduction to capacitance, inductance and AC theory; the description of phase contrast microscopy with terms such as "this is done by inserting a glass phase ring in plane P", with no explanation of phase rings, will leave students who have only the basics floundering; and in a similar manner the introduction to electron microscopy and the wave nature of moving electrons is badly skimmed. Throughout the text there are curious statements which suggest that the book was written to meet a deadline. On page 5 it is stated, "It is a common experience that when a stationary object is pushed sufficiently hard it moves".

Later (p 35), we have, "The eye is sensitive to light because the retina responds to the electric field". About ionic conduction through membranes it is stated (p 84), "The permeability of the membrane for Na^+ ions is less than that for K^+ and Cl^- ions so that when the fibre is in its normal state there are more Na^+ ions on the outside than inside". There are too many statements of this kind to unreservedly recommend it for reading by biologists as an introduction to physics.

John A. Sirs

John A. Sirs is Reader and Head of the Department of Biophysics at St Mary's Hospital Medical School, University of London, UK.

Insights into biological phenomena

Introductory Biophysics. By F. R. Hallett, P. A. Speight and R. H. Stinson. Pp 243. (Chapman and Hall: London 1978.) Paperback £5.95.

THERE is currently a need for a comprehensive modern textbook on biophysics suitable for university students. There are, of course, many books which are in effect physics primers for biologists, but

what is required is rather a book that illustrates the great insight into biological phenomena that can be gained from the application of physics. This book falls into the latter category. It not only describes the application of classical physics to biological phenomena but also covers the more modern areas such as the biological effects of electromagnetic and ionising radiations and the application of X-ray crystallography to biological molecules. Thus, physics is brought in as a tool to solve problems rather than as an end in itself. One can criticise the book for omission of some important topics—for example, thermodynamics and respiratory processes—but for a book of its size it covers a reasonable range. Furthermore, it is good to find a book aimed at the life science student which does not attempt verbal gymnastics in order to avoid a mathematical description of a process, and one that lays considerable emphasis on problem solving to consolidate concepts in the mind of the student.

Unfortunately, although the book has many good points, it is nevertheless something of a disappointment on two counts. The first is a lack of balance apparent in some of the chapters. It is, for example, difficult to understand how a chapter labelled 'molecular biophysics' can contain a discussion of protein structure and yet not show even one diagram of a protein model, and contain only one paragraph on how the modern understanding of the architecture of such molecules allows an interpretation of their function at a molecular level. Similarly, in the chapter on radiation biophysics, a good section on target theory is followed by a trivial discussion of the actual damage that ionising radiations can cause; furthermore, in such a chapter surely the biological and medical applications of ionising radiations deserve mention.

A second area of disappointment lies in the terse manner in which many crucial concepts are covered. This may be acceptable in a revision book, but this is clearly meant to be a primary text

and as such these concepts deserved a fuller treatment. To give only two examples: if, as occurs in chapter 7, it is necessary to have a section explaining the physical meaning of the terms work and energy, then more than the two paragraphs given are needed for adequate coverage. Similarly, in the chapter on heat flow in biological systems the phenomena of convection and radiation are explained at some length but conduction is not explained at all except in so far as the relevant equation is given. Indeed this particular chapter is rather poor because, though many of the ways in which heat may be lost by an animal are explained the control of heat production and loss in animals is described in so disjointed and incomplete a manner that it would be difficult for the student to obtain a coherent picture.

So we are still in need of a really good textbook on Biophysics, for, although this book does contain some very good material, it is frequently marred by omission and inadequate presentation.

Bioenergetics

THE main effort of research in bioenergetics, as shown by a glance through a journal such as *Biochimica et Biophysica Acta Bioenergetics*, is at present devoted to the biochemical details of energy transfer in mitochondria, chloroplasts and bacteria. However, underlying these processes are the basic physical principles embodied in the laws of thermodynamics (from which the concept of energy is derived), and quantum mechanics. These principles are the subject of *Foundations of Bioenergetics* (Academic: New York and London; \$26.50; £17.20), by Harold J. Morowitz.

The teaching (or rather the learning) of thermodynamics always seems to entail special difficulty. It is as if a deep gulf divides the majority of humankind who are baffled by, or ignorant of the subject, and those who feel they understand it. Morowitz leads the way across this gulf with confidence, carefully explaining where all the postulates of this strange discipline come from. Statements are punctuated by (definition), (empirical generalisation), (postulate) or (conclusion). The introduction of the method follows the conventional way of physical chemistry; steam engines and information theory both feature in the description of entropy. The treatment is quite rigorous. Biologists may be daunted by the variety of mathematical methods that are used, from calculus to Boolean algebra, but these are all given some introduction.

The book then continues into statistical mechanics, approached from a quantum mechanical viewpoint. Frequent references are made to the relevance to biological systems, from cells to ecosystems. The power of thermodynamics and statistical mechanics lies in their ability to draw wide-ranging and sometimes unexpected conclusions on topics such as the origin of life. In a section, "Life at absolute zero", he notes that "structure is the result of where the molecules [in a living system] are located, and function is a description of where they are going". From this, and the observation that simple life forms can survive freezing to very low temperatures, we are forced to the conclusion that the process of originating living material reduces to a problem of synthetic chemistry. Finally, it must be admitted, however, that there are severe limitations to the applicability of equilibrium thermodynamics (or 'thermostatics') to biological systems which are in a state of flux, and the later chapters cover fluctuating systems and the approaches to irreversible thermodynamics. These too have their limitations, caused by the complexity and non-ideal behaviour

of living systems, but the book provides a good introduction to these potentially useful methods.

In the 15 years since the publication of Lehninger's classic monograph *The Mitochondrion* (W. A. Benjamin: New York and Amsterdam), there have been considerable advances in our understanding of this organelle. These are documented in many books for the specialist and symposium proceedings, but it is surprisingly difficult for undergraduate students to obtain a straightforward overview of the present state of the subject. *Mitochondria: Structure, Function and Assembly* (Longman: London and New York; £3.75), by Peter A. Whittaker and Susan M. Danks, is designed to fill this gap. In price and length it is the sort of book that students of biology and biochemistry are likely to buy and read through. In condensing a large amount of research data, however, inevitably some of the excitement is lost. In reading the section on the mechanism of coupling between respiration and phosphorylation, there is only a faint echo of the spirited debate that has enlivened the Biochemical Congresses of the past ten years. The three major hypotheses are described and their merits are discussed; and it is con-

cluded that Mitchell's chemiosmotic theory is the most acceptable explanation of the available data (a conclusion recently endorsed by the Nobel committee). Oxidative phosphorylation may be the keystone of mitochondrial function; but despite the attention devoted to it recently we should not forget that many metabolic processes take place within the organelle, and here these are accorded their due weight.

The book is divided into five chapters: structure and isolation of mitochondria; tricarboxylic acid cycle and fatty acid oxidation; oxidative phosphorylation; transport across membranes; and mitochondrial assembly. The descriptions are punctuated by brief details of experimental methods, and general references for further reading are given at the end of each chapter. Advanced students may find that they need a more comprehensive set of references and will need to plunge into the specialist literature. However, this is a well balanced account, up-to-date and without frills. It should be a bestseller.

R. Cammack

Richard Cammack is Lecturer in the Department of Plant Sciences at King's College, University of London, UK.

Membrane functions

Membranes and their Cellular Functions. Second edition. By J. B. Finean, R. Coleman and R. H. Michell. Pp. 157. (Blackwell Scientific: Oxford and London, 1978.) Paperback £4.80.

OPENING the first edition of *Membranes and their Cellular Functions* was a great surprise as one found the excellent cartoons by T. A. Bramley. The authors are doing a valuable service in showing the reader that scientists are not deadly serious data-processing robots. We should also remember that students need some light relief during the work of absorbing the great mass of information presented to them. The sympathetic attitude of the authors also comes over in the text; they are not trying to impress with their sophistication but are simply and clearly telling the reader about biological membranes.

The first edition was excellent for supplementary reading but I felt that some of the more molecular aspects received rather scant treatment. In this new edition, although the original material and style has been retained, the subject matter has been re-arranged and not only brought up to date but considerably expanded, particularly in the molecular aspects. For example,

membrane structure and composition, mechanisms of solute movement across membranes—including the ion-translocating ATPases, energy coupling by ion gradients, neuro- and hormonal transmitters, and recognition responses—are now fully described. The result of this revision is the ideal book to cover the membrane section of a first- or second-year course in biochemistry, physiology or cell biology. It fills a gap at this particular level; Harrison and Lunt's *Biological Membranes* (Blackie: Glasgow and London, 1975) and Quinn's *The Molecular Biology of Cell Membranes* (Macmillan: London, 1976) being more detailed and suited to final-year courses, whereas Davies's *Functions of Biological Membranes* (Chapman and Hall: London, 1973) is rather elementary and now somewhat dated.

Our second-year students will be left in no doubt that they should read this book. Any students who have not encountered a course on membranes should read it in the long vacation before a final-year course in biochemistry, physiology or microbiology. Excellence does not mean perfection and there are, of course, some faults. What is called the Nernst equation (p86) is really the Henderson equation for diffusion potentials; the Nernst equation for equilibrium potentials is not given. This omission may explain the misconception on p75 where it is stated that the distribution of Rb^+ ions

Announcing a Major New Journal

Photobiochemistry and Photobiophysics

Managing Editor:

H. METZNER

Institut für Chemische Pflanzen-physiologie

Universität Tübingen, Corrensstr. 41, 7400 Tübingen, Germany.

Aims and Scope

The journal will provide an interdisciplinary medium for the rapid publication of concise papers on all aspects of photobiochemistry and photobiophysics. Contributions in related fields such as the photochemistry of biologically relevant compounds, model reactions and data processing of visual systems are also acceptable.

Papers may include new experimental results, description of new methods or new interpretations of existing data. Purely descriptive contributions as well as the presentation of preliminary and inconclusive results are discouraged.

The journal will also publish book reviews and announcements of important meetings.

Transport by Proteins

Proceedings of a Symposium, held at the University of Konstanz, West Germany, July 9-15, 1978.
 FEBS Symposium No. 58

1978. 17 cm x 24 cm. XV, 420 pages.
 Hardcover DM 145,- ISBN 3 11 007694 2

This book presents the proceedings (lectures and discussions) of a Symposium on "Transport by Proteins", held at the University of Konstanz. Well-known scientists discuss general problems, selected transport proteins, membranes and transport by proteins, metal transport by proteins and the molecular aspects of transport by proteins in physiology and pharmacology.

The topic covers a wide range of different systems of fundamental physiological significance, such as the transport of oxygen, metabolites, metal ions, drugs, hormones etc., all mediated by proteins, either in aqueous solution or through membranous structures, including multi-enzyme complexes and the oxidation-reduction chains of respiration and photosynthesis.

Use of ion gradients

Taken from Membranes and their Cellular Functions, reviewed on this page

"at equilibrium neutralises the $\Delta\psi$ (membrane potential)"—if it did it could not be used to measure the membrane potential. On p44 the unfortunate Nernst suffers again, $\frac{d\psi}{dx}$ being described as the charge, instead of the electrical potential, gradient. In my own research field, mitochondrial bioenergetics, I would quibble with the authors' selection and acceptance of some of the very recent data. I am sure others will find the same with their own speciality but this will not seriously affect the student or non-specialist reader: if it stimulates discussion with lecturers so much the better.

A more general criticism is that abbreviations tend to be thrown into the text leaving the reader to search

figures or tables to find their meaning. Also, although the lists of further reading at the end of each chapter are suitably short and carefully chosen, I felt that more help should be given to students in relating articles to particular topics. Further use of the wide margins could be made for both this and explanation of abbreviations.

These are all relatively minor criticisms and do not alter my view that this is now a really excellent book. It is accurately printed in attractive typeface on good paper making it, with the authors' style and the illustrations, a real pleasure to read.

M. J. Selwyn

Michael J. Selwyn is Senior Lecturer in the School of Biological Sciences, University of East Anglia, Norwich, UK.

Biochemistry texts

THREE recent biochemistry texts reflect different approaches to the student market.

The second edition of *An Introduction to Practical Biochemistry* (McGraw-Hill: New York and London, £6) is wide-ranging in its scope, describing in all some 140 simple experiments that can be carried out in any reasonably equipped biochemistry teaching laboratory. It is simply and clearly written. Descriptions of experimental procedures are interspersed with accounts of the appropriate underlying principles. In some cases I feel that this aspect of the book is rather overdone and would best be left to a general textbook. Experiments are adequately described together with lists of quantities of reagents and equipment needed for a given number of students. The book leans heavily to the physical and chemical rather than the physiological side of the subject. There are sections dealing with pH and buffers, separation methods (dialysis, gel filtration, column chromatography, partition chromatography, electrophoresis), colorimetry and spectrophotometry, protein isolation and N-

and C-terminal determination, artificial membranes, nucleic acids (base-composition, isolation and estimation), simple enzyme kinetics and also rather extensive sections dealing with qualitative and quantitative tests for sugars, amino acids and lipids. The final chapter, entitled "Metabolism", contains experiments of the more physiological type including isolation of mitochondria and chloroplasts, adipocyte isolation and metabolism, intestinal transport of amino acids, glucose fermentation by yeast, bacterial growth and β -galactosidase induction and a few whole-animal experiments. In general, quite a good book that is suitable for use in the first two years of a biochemistry degree course.

Basic Biochemistry: A Visual approach for College and University Students (Heinemann Educational: London, £2.90), by J. Edelman and J. M. Chapman, might appeal to some who like a smattering of biochemistry presented in 'comic-strip' form. Personally, I hated it. The book is in three sections. The first deals with the components of the cell, proteins, carbohydrates, lipids and nucleic acids, and in my view is the best part of the book. From this an elementary student should gain some feel for the basic structures in the cell, without gaining

such idea about their chemical properties and reactions or the chemical principles underlying these. The second section deals with enzymes and attempts to explain enzyme kinetics and action with the aid of a multitude of diagrams (which in many cases are rather scrappy) and no mathematics at all. I think a student is more likely to be confused rather than informed by this section. The third and largest section deals with metabolism. Here again, the use of a plethora of rather scrappy diagrams seems more likely to sow confusion than understanding. The treatment of much of intermediary metabolism is scimpy and there is no attempt to set it in a physiological framework. There is also a heavy use of terms such as 'high-energy bond', 'energy release' and 'energy trapping' which often are not appropriate. This book might be suitable for a student with little previous chemistry who is required for some reason to acquire a veneer of biochemistry, otherwise, it is not suitable as a serious biochemistry book.

Amino Acids, Peptides and Proteins: An Introduction (Macmillan: London; £15), by E-D. Jakubke and H. Jeschkeit is really a specialist book which might be of use as a reference text for final-year undergraduates taking an Honours degree in biochemistry or chemistry. Visually, the book is rather unattractive, having plain diagrams and a small type-face. On the other hand, the amount of information it contains is considerable. The book falls into three parts. The first deals with the amino acids; their classification, physical properties, synthesis, analysis and reactions. The second part covers peptides—in particular, synthesis (problems encountered in the latter, general strategy, together with detailed methods). In fact one third of the entire book is given over to peptide synthesis. There is also an interesting section dealing with an extensive range of important naturally occurring peptides. The third part deals with proteins and covers classification, physicochemical properties, isolation and purification, sequence analysis and structure. The text is quite readable and does not seem to have suffered in the course of translation from the German version. The book is interspersed with frequent reference sections which by now are not very up-to-date (1972–74 are the latest references). In conclusion, a useful book, more to be used for reference than as a student's reading book.

E. D. Saggerson

E. D. Saggerson is Lecturer in Biochemistry at University College, London, UK.

Insect biochemistry

Biochemistry of Insects. Edited by M. Rockstein. Pp. 649. (Academic: New York, San Francisco and London, 1978.) \$29.50; £19.15.

IN 1961 Darcy Gilmour's book *The Biochemistry of Insects* (Academic: London) was published and in a text of under 300 pages it covered the available information on insect biochemistry, and included a generous amount of background information on general biochemical principles. The growth of the subject in the intervening years has been prodigious and to effectively review the field in a book that is little more than twice the size of Gilmour's is no mean achievement. The book that Morris Rockstein has edited covers the ground admirably. Its production and format closely resembles the six-volume revision of *The Physiology of the Insecta* produced by the same editor, and publisher in 1974, and these two works will stand as a major source for entomology students for many years to come.

The majority of undergraduates who undertake specialist entomology courses these days will have received some basic biochemical training and this is essential if maximum benefit is to be derived from this book. However, it is not simply an exposition of the biochemical specialisations to be found in the *Insecta*. The authors have each taken the trouble to fit the biochemical facts into the wider biological picture and no matter what aspect of entomology interests the reader, he or she will find valuable facts and ideas within this book.

Inevitably, in any work which is compiled from several contributing authors there is some lack of uniformity in approach. To quote one example, the chapters on carbohydrates and lipids deal with the nutritional requirements for these compounds, and with their digestion and absorption, but no corresponding information is available in the chapters on proteins and amino acids. A lack of uniformity is also evident in the references to original literature, the chapter on insect biochromes having a bibliography of more than 30 general references and about 140 specialist references, whereas that on the toxic action of insecticides has only five general references. The separate listing of general works in the bibliographies is an admirable idea for the undergraduate reader interested solely in reviewing a particular topic. On the other hand the postgraduate reader who consults those chapters where

specialist references are lacking, will require access to several other reference works before the original papers can be tracked down.

This very readable book is a valuable and significant contribution to the entomological literature. It provides important background information for

undergraduate courses and will be a standard reference work for a wide range of professional entomologists.

Biochemistry of viruses

The Biochemistry of Viruses. By S. J. Martin. Pp. 145. (Cambridge University Press: Cambridge, 1978.) Hardback £10.50; paperback £3.95.

KNOWLEDGE of the nature and biosynthesis of viruses has progressed to a stage where it is clearly impossible to encompass all aspects of the biochemistry of viruses in the space of 145 pages. The author of this latest volume in the series *Cambridge Texts in Chemistry and Biochemistry* has adopted a sensible compromise presenting a coherent survey of the subject based largely on his own experience and interests. The text progresses from a brief but adequate review of the history of virology through chapters on classification, assay, purification, structure, strategy of infection (that is, transcription, replication, maturation, defectiveness), therapeutic and prophylactic agents, and evolution. The book begins and ends on a philosophical note contrasting the virus as the invader of the genosphere with man as the invader of the biosphere.

The best and most comprehensive portion of the book is the chapter on virus architecture. The chapter on strategy of infection, which takes up 54 of the 145 pages, is well written but is less satisfactory, as it fails to deal adequately with the animal DNA viruses and the RNA tumour viruses. The text also suffers from having been prepared before the application of restriction endonucleases to analysis of

the structure of the genomes of DNA viruses. In my view these deficiencies, together with the virtual exclusion of genetics, will limit the usefulness of this book as a course textbook. It can be recommended, however, as supplementary reading because Dr Martin has a lucid and simple style of writing which provides the hard-pressed student with an excellent example of the organisation and presentation of information in essay form.

Over-simplification occasionally generates inaccuracies such as "all RNA tumour viruses . . . appear to have similar base sequences" (p123); "most DNA viruses contain circular DNA molecules" (p44); and the like. Also a number of errors have slipped through. For instance, part of Figure 5.26 is missing; two eminent virologists have their names mis-spelt; the molecular weight of herpes simplex virus DNA is given variously as 54.92 (Fig. 2.4), 75 (p92) and 80-100 (Appendix) million and that of oncornavirus RNA as 10 million (Fig. 2.5). The retroviruses do not appear in the virus classification in the Appendix, apart from Rous Sarcoma virus which is listed as the prototype of the genus coronavirus of the family rhabdoviridae.

These imperfections will be sufficiently obvious to most readers not to detract from the basic worth of the book as a simple introduction to the biochemistry of viruses.

C. R. Pringle

C. R. Pringle is a member of the scientific staff of the Medical Research Council Virology Unit in the Institute of Virology, University of Glasgow, UK.

Molecular genetics

THERE have been three exceptional textbooks written about microbial genetics. These are *The Genetics of Bacteria and their Viruses* by W. Hayes first published in 1964, *The Molecular Biology of the Gene* by J. Watson first published in 1968, and *Molecular Genetics* by G. Stent which was first published in 1971. These books cover a lot of similar territory, but each has a distinctive flavour. In Hayes' treatment the development of the subject

seems a trifle disorganised in places, but the book is written with a sense of enthusiasm and wonder which is quite infectious. Watson's approach is autocratic, or "sovereign didactic" to quote the felicitous if somewhat ambiguous description from Stent. One has the feeling that no matter how cells originally functioned that after reading Watson's book they would have considered it advisable to conform to the royal dogma. Stent's book is undoubtedly the most literary of the three. He set out to write an introductory narrative and the book tells the story superlatively well.

Of these books Hayes came out in a

second edition in 1968 so is now in need of revision, Watson had a third edition published in 1976, and a second edition of *Molecular Genetics* (Freeman: San Francisco and Reading; hardback £14, paperback £9.70) has been prepared by Stent in collaboration with R. Calendar. The new edition retains the greater part of the original text (605 pages) and adds to it about 150 pages of new material either in the form of extra paragraphs or plates inserted at strategic places in the narrative, or by completely new sections added to relevant chapters. An examination of the small modifications which have occurred to the old text gives a fascinating insight into some alterations which have happened over the years to scientific language interpretation and technique. For example, the heading "The sex factor as an episome" has become "The fertility factor as a plasmid" and in the same vein "The conjugal tube and mobilisation" is now "The conjugal bridge and mobilisation". Also, the classic autoradiograph of a bacterial chromosome by Cairns has been re-interpreted to allow for bidirectional replication, and some unspecified development has introduced substantial changes to the curve depicting the kinetics of ONPG hydrolysis by β -galactosidase resulting in a threefold drop in affinity constant. One sad loss, no doubt inevitable because of cost considerations, is the four colour plates of the original edition, particularly that by I. M. Wallace of eye-coloured mutants in *Drosophila*, which is a work of art in its own right. A less comprehensible omission is that of the Newcombe resspreading experiment. This is the example I would propose to students if asked to name a single experiment as an ideal they should aim for in their research. It is, ingenious, simple in principle and practice, and unambiguously proves its point. When this edition is reprinted perhaps the missing two pages could be added as a supplement by way of expiation.

The more extensive new sections are written in the same style as the original and have up-dated the text on a selection of topics including DNA replication, gene expression, RNA phages, genetic engineering, transcription and translation. However, the limited scale of the revision couldn't hope to do justice to all the advances that have occurred in the past 8 years, so there is little discussion of recent developments in a number of other areas—for instance, in DNA repair, plasmids or transposons. Nevertheless this edition is the most useful text available at present for teaching introductory courses in molecular biology. It is not, however, a contemporary classic like its progenitor was in its time. There is still a real need for a completely new and comprehensive treatment of the subject.

Two books by D. Freifelder are more specialised aids to teaching. *Molecular*

Biology and Biochemistry: Problems and Applications (Freeman: San Francisco and London; paperback £4.10) is a useful text in the manner of *Biochemistry: A Problems Approach* by Wood, Wilson, Benbow and Hood (W. A. Benjamin: New York). Each of 17 chapters starts with a concise introduction to a particular topic, and this is followed by some references and a collection of relevant problems. Answers to the 550 problems are supplied at the back. The book will be of considerable use to both elementary and advanced students.

The DNA Molecule: (Freeman: hard-

back £13.40, paperback £7.40) contains a collection of 44 original articles arranged in sections, each of which has a short preface and is concluded with some pertinent questions and references. The collection has a structural rather than genetic bias and although it will be a useful reference book for microbial geneticists its role in teaching is more likely to be in courses of biophysics or structural molecular biology.

N. Symonds

N. Symonds is Professor of Microbial Genetics at the University of Sussex, Brighton, UK.

Textbooks of genetics

Most textbooks of genetics seem to fall into three main categories: those designed for an educated general readership, those designed for university students taking courses in which genetics is not a major topic (for example, social sciences and medicine) and those designed for students with a specific interest in genetics. However, Sam Singer's slim (139 pages) *Human Genetics: An Introduction to the Principles of Heredity* (Freeman: San Francisco; paperback £3.10) does not fit easily into any of these categories. It is a very nicely presented summary of some of the essentials of human genetics, but it is difficult to know for whom it might be of value. It is too technical for the general reader or advanced school student and yet would be inadequate for an undergraduate course in human genetics. This is a pity because the author is clearly equipped to write a fuller text which undoubtedly would be very appealing to undergraduates. On the credit side I would rank it highly in being remarkably up-to-date, accurate and very readable. The illustrations are simple but of a particularly high quality. This is presumably a reflection of the publishers' association with *Scientific American* which features prominently among the suggested readings at the end of each chapter each of which also concludes with a summary. There is an Appendix of 25 problems (with answers) mainly concerned with what is often loosely referred to as "pedigree genetics".

Two recently published books on population genetics illustrate very well the differing approaches to the subject. One is designed for the relatively non-specialist undergraduate (Bryan Shorrocks; *The Genesis of Diversity*; Hodder and Stoughton: London; hardback £5.75, paperback £2.95), the other for the specialist undergraduate or postgraduate (Eliot B. Spiess; *Genes in Populations*; Wiley: Chichester, UK, and New York; £13.95). I would warmly recommend both of these books to the readership to which

they are directed. Both deal with factors affecting gene frequencies in populations, natural selection, polymorphisms and the underlying genetic basis of individual variations. But whereas Shorrocks concentrates more on the biological aspects of variation and requires no more than a basic knowledge of simple algebra, Spiess' approach is largely based on mathematical reasoning. Regarding the *Genesis of Diversity* most examples are chosen from *Drosophila*, a field in which the author has made his own contributions. Industrial melanism in moths (*Biston betularia*) is also given special attention. It seems odd that there is no mention of Clarke's work on frequency-dependent selection (though the subject itself is discussed), and there is very little about the population genetics of man. The latter is particularly unfortunate because this is an aspect of the subject which is rapidly growing in interest and importance. The presentation is clear and is well illustrated with line drawings and graphs. There is a list of well chosen references and an index. In its field it will have a number of competitors but as a straightforward and well written introduction to the subject it will no doubt be welcomed by many students and their teachers.

Whereas Shorrocks' book can be read from cover to cover in a couple of evenings, Spiess' book would defy any such approach. It is, at least to me, a book to dip into. A knowledge of differential calculus and matrix algebra, though not essential, would certainly make for a fuller appreciation and understanding of the text. There is, however, a very helpful appendix of various mathematical and statistical formulae used in the text. This too is a very attractive book and the way the material is clearly divided into well defined sections is very helpful to the reader. Also, examples are chosen from a wide range of organisms including man. Unfortunately, though each chapter concludes with a number of questions, no answers are provided, which is unhelpful to students and a possible source of embarrassment to teachers.

Alan E. H. Emery

Alan E. H. Emery is Professor of Human Genetics at the University of Edinburgh, UK.

Contemporary microbiology

Two recently published microbiological textbooks are aimed at opposite ends of the student market. One comes close to the bull's-eye of its target. The other discharges its material with all the accuracy of a sawn-off shotgun. *Essays in Microbiology* (Wiley: Chichester, UK; £13.50), edited by J. R. Norris and M. H. Richmond, is a set of sixteen chapters (not, in my opinion, essays) of exactly equal length. The readership is expected to be "the early stage undergraduate student with some topics of relevance to the senior school pupil". *Companion to Microbiology* (Longman: London and New York; £12), edited by A. T. Bull and P. M. Meadow, consists of nineteen chapters of varying length and format covering a wide range of topics chosen for a readership of "advanced undergraduate and postgraduate students".

The editors of *Essays* have declared as one of their objectives a need to inform the undergraduate embarking on a microbiology degree course just what he is letting himself in for and they wisely achieve a balance between the descriptive and molecular aspects of the subject. The editors of *Companion* have solicited articles from experts in some of the growth areas of microbiology and have included topic neglected in recent textbooks "for discussion in broader perspective than is usual in review articles and in more depth than is possible in a general textbook". The latter formula sounds very much like that of an essay and, indeed, the chapters in *Companion* are very much more like essays than are the sections in *Essays*.

With new texts for the student market appearing with a frequency approaching that of new bacterial species in the hey-day of descriptive microbiology, the reviewer must clearly advise the potential consumer as to whether the various objectives of the editors and authors have been achieved and whether the publishers have been able to offer value for money. It is difficult to avoid a comparative approach when reading two books such as these and, at the risk of being unfair to *Essays*, I feel obliged to comment that *Companion* is more successful in achieving its stated objectives and much better value for money than *Essays*. Having made this judgement, and because the articles in *Essays* are on sale separately I shall devote more space to this volume than to the other.

Professor Stanier's contribution, "What is Microbiology?", maintains the high standard we have come to expect from this source and the article by one of the editors, Professor Rich-

mond, on "Genetic organisation in bacteria and its expression" is equally successful. Four chapters on form and function in bacteria, fungi, viruses and protozoa are of variable quality. Dr Murray's article on bacteria adopts a cytological and ultrastructural approach but there is some careless proof-reading which detracts from its intelligibility in places. The chapter on fungi (Dr Booth) is a dull, detailed descriptive survey which will not generate much enthusiasm for mycology amongst younger readers. The viruses are better served. Professor Watson succeeds admirably in presenting the intricacies of virus structure, particularly that of icosahedral viruses, in a lucid manner. Herpes may not be so simplex these days but the author manages to express the most complex geometrical concepts in a manner which would be understandable to an advanced school student and stimulating to a final-year undergraduate. Alas the protozoa suffer much the same fate as the fungi, although the authors (C. R. Curds and C. G. Ogden) are mercifully less obsessed with taxonomy than Dr Booth. The chapter begins rather well with the taxonomy compressed into a page of suitably small print, but one soon encounters phrases like "In tectinous allogromiid foraminifera . . ." without either warning or explanation. Such experiences tend to have a somewhat anaesthetising effect on the non-specialist.

One curious feature of these two books is that one of the co-editors of each has an article not in his/her own book but in the other, which all goes to emphasise what a small universe we microbiologists inhabit. Thus Professor Norris writes for *Companion* and Dr Meadows, a co-editor of *Companion* writes on "Chemistry and composition of micro-organisms" in *Essays*. Her contribution gets to grips with the structure/function relationship very well and a reader with a good background in structural biochemistry could gain much by reading it. However, readers with ordinary level German will be surprised to learn that the nomenclature of O and H antigens derives from "the German *ohne Hauch*, without whip"! I think that the intended readership would find Professor Tempest's approach to "Dynamics of microbial growth" rather dull and theoretical. He considers the ecological implications of substrate-limited growth only very briefly and some mention of the growth rates of organisms in their natural environments or the implications for industrial microbiology would have made the chapter more interesting. "Intermediary metabolism" is covered by Professor Clarke in a clear and interesting account which is well-directed at the target set up by the editors.

Professor Sneath has been permitted two bites of the cherry with separate chapters on "Classification of Microorganisms" and "Identification of Microorganisms". Both these articles are at an advanced level inappropriate for this collection. They would in fact have fitted in much more comfortably in *Companion*. Professor H. Smith's chapter on "Determinants of Microbial Pathogenicity" is a good summary of the field and its future prospects but is necessarily rather superficial. Some line drawings, diagrams or photographs would have added to its impact. The rather more specialised topics, "Interactions between phage and bacteria" (Kay), "Resistant forms" (Slepecky), "Symbiosis in the microbial world" (Smith) and "Bacterial nutrition" (Whittenbury) will find interested readers at several levels.

As the individual contributions to *Essays* were written to be available separately some duplication of material was inevitable and even desirable. Nevertheless there is too much of it. Some authors show an awareness of the content of the contributions of others, but in other cases there is needless repetition. In contrast there is little duplication in *Companion* and some useful cross-referencing between chapters. The editors of *Companion* did not impose fixed-length or other formats upon their contributors but the book achieves a remarkable cohesion. The print is small but very clear and the quality of the illustrations and photographs excellent. The nineteen topics chosen reflect to some extent the idiosyncracies of the editors (or those of their friends) but the book is none the worse for that. The topics range wide and most are of direct relevance to contemporary microbiology courses. It is a pity therefore, that they too cannot be purchased as separate offprints by students. However, I feel much more confident in recommending the whole of this book as a cohesive collection than I do about *Essays*.

At £13.50 *Essays* is rather poor value as the articles are of variable quality and aimed at too many targets, but I do recommend teachers and students to look it over and purchase the offprints which interest them. Best buys are Stanier, Richmond, Clarke, Watson and Slepecky. At the lower price of £12 *Companion* is excellent value. The size and format allow for the text to be approximately twice the length of that of *Essays* and the editors and publishers have turned out an attractive authoritative book.

G. E. Mathison is Lecturer in the Department of Microbiology at Queen Elizabeth College, University of London, UK.

Microbiological dictionary

Dictionary of Microbiology. By P. Singleton and D. Sainsbury. Pp. 481. (Wiley: Chichester, UK, and New York, 1978.) £17.50.

It seems to me that two sorts of useful dictionary could be compiled for microbiology. The truly comprehensive dictionary would be a large scholarly work and probably could only be written by five or six people. But to have a single reference work for the whole terminology of this subject (stretching from phytoplankton ecology to the molecular biology of animal viruses) would be of enormous value. The second sort of dictionary is not comprehensive and is of little use to the professional microbiologist but can be of great value to those who lack a microbiological background yet who need to know about some aspects of microbiology in association with another main interest.

The authors' preface indicates that this dictionary is intended for undergraduates and postgraduates in microbiology but I think it is only likely to find a place in my second category. Microbiology students would find little

in the dictionary which was not covered at least as well by their textbooks, even if they have only a very small collection. The complete absence of any references to source of information or to more detailed literature would also reduce the use which could be made of the contents.

The authors have set out to cover "pure and applied microbiology, biochemistry, immunology, genetics and . . . microbiological aspects of allied subjects such as medicine, veterinary science and plant pathology". This is probably too wide a range of material to encompass in less than 500 pages and has led to omissions. Although I was not surprised that there is no entry for *Sterigmatomyces*, it is unfortunate that for instance *Trichoderma* and *Dunaliella* are not included; that is, the choice of organisms has been rather arbitrary, with some very obscure genera included and some important or commonly used ones left out. Comparable examples are the absence of bacteriophages μ and P1, which have an important place in microbial genetics.

The coverage of biochemical terms may equally be criticised for the lack of entries concerning microbial products that are of interest in a wider context, such as pronase, subtilisin and taka diastase. A much fuller account of restriction endonucleases would also have been a timely improvement.

The cross reference of one entry to another is not thorough. For instance, although the entry "red tides" attributes this phenomenon to the alga *Gonyaulax*, the entry "*Gonyaulax*"

makes no mention of red tides. Similarly, although the Helmstetter-Cooper model of the bacterial chromosome replication cycle is described at some length under 'growth (bacterial)', the entry "Cell cycle" does not refer to it. Indeed, the entry for "Cell cycle" gave me the clear impression that this term is only used with reference to eukaryotic (usually mammalian) cells, which is misleading.

Coverage of growth physiology and fermentation is poor, with a wide variety of omissions. There is no mention of substrate-accelerated death, maintenance energy or fed-batch culture, which are the kind of terms which non-microbiologists are most likely to seek for definition in a subject dictionary of this sort. The description of continuous culture is very sketchy.

An appendix of metabolic pathway schemes is included, which is a laudable idea, but again the selection is not beyond criticism. Why the tricarboxylic acid cycle is in this appendix whereas the reductive pentose phosphate cycle is in the main body of the text (under "Photosynthesis") is not obvious.

Recognising the limitations of space I feel that many will share the view that too much space has been devoted to material which can easily be found in the literature of biochemistry, genetics and general biology at the expense of many microbiological terms and ideas which could so usefully have been included.

Christopher F. Thurston

Christopher F. Thurston is Lecturer in Microbiology at Queen Elizabeth College, University of London, UK.

Steady-State Enzyme Kinetics

Stanley
Ainsworth

Identifies the basic ideas of the subject for the graduate and advanced undergraduate student, and familiarises the reader with them so that they may then be applied to any problem likely to be encountered.

Although it cannot altogether avoid mathematical presentation, almost all the equations used require only an elementary acquaintance with algebraic manipulation. Moreover the arguments themselves are presented as fully as possible to enable the reader to progress easily from each stage to the next.

M MACMILLAN
PRESS

Basic phycology

In the introduction to *Introductory Phycology* (Wiley: Chichester, UK; £12.25), F. R. Trainor stresses the importance of consulting more specific works in order to learn how new information is added (to the science) and older facts and interpretations are modified or discarded. Such an outlook was clearly foremost in the author's mind when writing this book for throughout the book the different subjects are suitably placed in their historical perspective and questions are raised in areas deserving of attention in a way that a student might identify with the specialist researcher. The book is perhaps suitable not so much as a reference text but to be read straight through as an introduction to the subject. As such it is well conceived. The author succeeds in conveying his interest and enthusiasm with style and the layout has obviously been

given a good deal of consideration.

Following two introductory sections each of the algal groups is considered separately in twelve chapters, which should give the student a fairly comprehensive account of algal forms. In each of these Trainor deals with the morphological organisation, the characterisation and the reproduction of the class before considering representative genera and other features of special interest. The classification of each group has been deliberately kept to a minimum. Although this is laudable in many respects it might serve to confuse a student particularly in a group like the Chlorophyceae.

The succeeding chapters deal with algal habitats and distribution, classification and morphological variability of benthic organisms, the plankton and their environment, algal control, their usefulness and harmful effects, and finally their culture. In the course of these a good deal of interest is generated and many aspects are treated in

some detail, for example, the section concerning algal products. In the ecological sections the remarks on freshwater and marine environments are nicely balanced and indeed the algae discussed will be familiar to or soon encountered by students in the UK. *Introductory Phycology* is nicely produced and surely a well worthwhile investment for the would-be phycologist.

Illustrations are plentiful both as line drawings and half-tones, a few of which have their limitation. In this respect the book suffers a little by comparison with H. C. Bold and M. J. Wynne's *Introduction to the Algae* (Prentice-Hall: Hemel Hempstead, UK; £16.80), a work which is also a little more detailed in the taxonomic section but which lacks the very interesting general chapters of Trainor. Bold and Wynne's book is subtitled *Structure and Reproduction* and in the preface they declare that the reason for this emphasis is the existence of suitable treatments of algal physiology, biochemistry and genetics elsewhere. It is surprising therefore that the book lacks much ecological information, considering the fact that no equivalent text on algal ecology has been published recently. As an introduction it may for this reason fail to present the algae in their proper biological perspective.

Following a detailed introduction there are nine chapters devoted to the different algal taxa, followed by an appendix dealing with algal cultivation in the laboratory. Sadly Bold and Wynne do not consider whether the prokaryotic 'Cyanochloronta' should be included among the otherwise totally eukaryotic algae, although it would take courage to exclude the group from an algal textbook. However, this approach is consistent with the rest of the book in which the authors have lumped together taxa which would be kept apart by many other workers. For example the inclusion of the prasinoflagellates within the Volvocales may surprise some students and the grouping of the Chrysophyceae, Prymnesiophyceae, Xanthophyceae, Eustigmatophyceae, Bacillariophyceae and Chloromonadophyceae in the Chrysophycophyta on the grounds of similarities in storage products and general pigment composition will be regarded as a retrograde step by many phycologists.

Each chapter consists of general information at and above the ordinal level and a more detailed treatment of representative genera. Regular inclusion of dichotomous keys will help the student to recognise characters of diagnostic (and taxonomic) importance provided it is appreciated that the keys

are not comprehensive. It is a pity, however, that this format is not adhered to in all the sections, for example, those concerning the Cryptophycophyta and the Bacillariophyceae. The treatment of the diatoms is particularly disappointing and only about 20 pages are devoted to this group compared with 33 pages for the dinoflagellates and 186 for the Chlorophycophyta. Admittedly there is not a great deal of variation in basic diatom morphology but no genera are dealt with in detail and there is not one good illustration of a raphe.

Introduction to the Algae has as

Ecology textbooks revived

SINCE the population explosion of ecology textbooks some five or six years ago, there has been something of a lull in the field. Presumably the market has been saturated and the plethora of books then produced have entered the cut and thrust struggle for existence. During this time, book prices have risen sharply, and many of the texts by such authors as Ricklefs, Colinvaux, Krebs, McNaughton and Wolf have passed beyond a level where the undergraduate is likely to be able to afford them. As a result, my impression is that such authors as Odum and Komondy have risen like a phoenix from the ashes to re-establish themselves, as a consequence of their low price. Some new invaders in the field are reviewed here.

One of the current releases in Britain is R. E. Ricklefs' *The Economy of Nature* (Cheron, Oregon: £6.75). This, in fact, made an earlier appearance in 1976, but with Blackwells taking over its British distribution, it is more likely to make an impact on its second invasion. It was designed to bridge the gulf between the lengthy ecological tomes and the brief, introductory paperbacks. It is lucidly written, well produced and illustrated, and covers a very broad field from soils and plant geography to environmental physiology, population dynamics and community energetics. Refreshingly, it steers clear of the 'environmental crisis' syndrome. It is essentially very basic and descriptive in its aims. It avoids numerical data; even population dynamics are discussed without reference to mathematical formulae. In my opinion this is a disadvantage, but it may prove a useful way into ecology for those without a scientific background such as some students in the

social sciences, and some of those taking such courses as environmental studies may appreciate its simple approach.

Serious, potential ecologists I would direct elsewhere, possibly to Ricklefs' larger book *Ecology* (Nelson: Nashville, 1973).

J. L. Richardson's *Dimensions of Ecology* (Williams and Wilkins: Baltimore) also starts from a very basic level and avoids numbers wherever possible. Rather than attempting the very broad coverage of Ricklefs, Richardson picks out certain habitats and deals with these in some detail—namely, deciduous forest, fresh water habitats and deserts. Unfortunately, from a European point of view, these chapters have a very parochial, North American flavour. No doubt they will be far more valuable on that side of the Atlantic. The production quality of this book is not what it might be; many figures are very poorly produced. The style is extremely informal, even chatty, to which I have no objection, except where it leads to inaccuracy.

For example, when discussing the influence of succession upon biogeochemical cycling in forests, the author states that "we see ecosystems performing excellent plumbing jobs on themselves, repairing leaks in an efficient and seemingly co-ordinated fashion". Apart from the garish anthropomorphism of this statement, it implies (as does its full context) that the "leaks" are fully "repaired" at the climax. This, of course, is not the case, for nutrient discharge must increase as ecosystem growth (and nutrient demand) diminishes.

R. S. De Santo's *Concepts of Applied Ecology* (Springer: Berlin and New York: DM28, \$14) is another attempt at a basic, introductory text. It has certain unique features some of which could have been more fully developed with profit, such as the section on animal and plant physiology. A large portion of the book is given over to terrestrial, freshwater and marine

THE PHLEBOTOMINE SANDFLIES (Diptera: Psychodidae) of the ORIENTAL REGION

By D. J. Lewis

*Bulletin of the B.M. (N.H.)
Entomology series Vol 37 No 6. 1978.
128 pp including 345 references,
273 text figures and 13 maps, paper
covers.*

£17.85

This first survey of the known Oriental sandflies includes a key for use as an aid to identification in conjunction with original descriptions which are indicated by numerous citations. Descriptions include much information on the skin-piercing stylets which are related to kinds of host animals and thus link taxonomy with functional morphology. Study of the cibarium or buccal cavity of several species sheds new light on the structure of this organ which is important in the classification and blood-feeding process of sandflies. Special attention is paid to the vector of visceral leishmaniasis or kala-azar in India, *Phlebotomus argentipes*, which shows regional variation. This paves the way for cytotaxonomic work in relation to localisation of man-biting and disease transmission by this species. The known Oriental distribution of all species is shown by detailed lists and maps. There are sections on zoogeography, host-animal records and seasonal prevalence. A review of medical importance includes a summary of the relation of *P. argentipes* to kala-azar which is now causing an alarming epidemic in India.

Oxford Books for Students

Physical Chemistry

P. W. Atkins

'It is a book of its time not only in content and outlook but in format and style too . . . could well become a milestone in the development of textbooks of physical chemistry.' *Chemistry in Britain*. 'An important and original work.' *Education in Chemistry*. 'The author is to be congratulated on the production of such a good text and the publishers for its presentation at a price within the reach of students.' *British Book News*. £15 paper covers £7.95

Primary Metabolism

A Mechanistic Approach

J. Staunton

The traditional line of demarcation between biochemistry and chemistry has dissolved in recent years as chemists and biochemists have joined forces in investigating the mechanisms of reactions which take place in living systems. This book introduces this area of common interest to students of both chemistry and biochemistry. £6.50 *Oxford Chemistry Series 29*

Secondary Metabolism

J. Mann

'It is encouraging to see published a book such as Dr Mann's, which is designed for the undergraduate and beginning researcher. His book is very well put together and should facilitate and encourage the preparation of undergraduate courses on modern natural products chemistry.' *Chemistry in Britain*. £9.75 *Oxford Chemistry Series 27*

Numerical Solution of Partial Differential Equations

G. D. Smith

This substantially revised second edition covers linear and non-linear parabolic equations, the analysis of errors, first- and second-order hyperbolic equations, elliptic boundary-value problems, systematic iterative methods, consistent orderings of matrices, and recent methods for large linear systems. Second edition illustrated £9 paper covers £4.95 *Oxford Applied Mathematics and Computing Science Series*

The Bowels of the Earth

John Elder

This paperback reprint has replaced the boards edition which was published in 1976. 'Original, persuasive, intensely individual . . . the book is plainly a *tour de force*, and it may set a new model for scientific exposition . . . The prose . . . is direct and evocative.' *Scientific American*. Paper covers £2.95

Human Growth and Development

Wolfson College Lectures 1976

Edited by Jerome S. Bruner and Alison Garton

These papers explore some of the biological, social, and political factors involved in growing up in modern society. They indicate the strong admixture of biological and social determinants that influence behaviour during child development, and two main themes run through the book: the importance of achieving social connection, and the active nature of childhood. £4.25 paper covers £2.25

Mechanics and Motion

L. Mackinnon

This book, based on the first-year course given by the author at the University of Essex, provides a survey of those topics that are an essential background to modern physics and advanced engineering. Throughout, the emphasis is on the basic physical concepts necessary to a study of the more advanced courses that will follow. £6 paper covers £3.25 *Oxford Physics Series 17*

The Properties of Nuclei

G. A. Jones

This book describes the properties of nuclear levels, starting with stable states and progressing, via quasi-stable states (radio-active ground states and nuclear-stable excited states), to unstable (nucleon-emitting) states. The shell model, the collective models, and the optical model of the nucleus are described, and nuclear reactions are introduced in terms of the compound nucleus and direct processes. £5.95 *Oxford Physics Series 12*

Oxford University Press

habitats, but the most distinctive chapters are those dealing with the construction of an Environmental Impact Statement and with toxic compounds in the environment. The former, in particular has an emphasis on the practical issues of ecological survey, which undoubtedly stem from the author's personal experience. The other two unique features consist of a table of conversion factors 28 pages long (it even contains leagues to miles, and kilderkins to metres), and a glossary of 89 pages, which could be regarded as a dictionary of ecology. The latter is reasonably extensive in some areas, but others (for example geomorphology and soils) are not adequately covered. Some definitions are far too vague, for example marsh, bog and fen appear synonymous ('swamp', it seems, is dominated by trees).

Finally, we have two new plant geography texts. The bulk of R. Daubenmire's *Plant Geography* (Academic: New York and London: \$21.50, £15.25) consists of descriptions of plant communities in relation to climate and soils, with an almost complete concentration on North America. Only in the tropical section does Daubenmire step beyond the United States to any significant degree, and here the emphasis is mainly upon Mexico. Within these geographical constraints, however, the author has produced an interesting and informative book. It is obviously aimed at giving the North American student an understanding of his country's natural vegetation. Introductory chapters set the scene in terms of plant dispersal and limits and also provide a condensed account of the history of North American vegetation. It fills a gap in the literature and will undoubtedly be welcome in the USA.

A. S. Collinson's *Introduction to World Vegetation* (Allen and Unwin: London; £6.50) has a somewhat misleading title, for the bulk of it is concerned with general plant ecology, and only the last one third is devoted to the subject of the title, *sensu stricto*. All of the topics dealt with in the first part are treated more fully and more effectively in a variety of other texts, but the second part makes a real and useful contribution to the undergraduate literature. It deals with the world's major vegetation formations, but instead of listing plants, as so many texts do, it collates much interesting ecological information derived from current literature. Such features as soils, variations in vegetation with topography, productivity, and nutrient cycling processes, receive some prominence in Collinson's treatment. It is a shame that more space in the book was not given to this section and less

to the rather superficial account of plant ecology.

It is probably a semantic impossibility to define a vacant niche (in the Hutchinsonian sense), but there does seem still to be a vacancy in the ecology textbook scene for a low-priced, brief, and up-to-date introduction to the subject from a biological point of

view. Odum's *Ecology* (Holt, Rinehart and Winston) and Kormondy's *Concepts of Ecology* (Prentice-Hall) still hold their own in this sphere, but this may in part be due to lack of competitive challenge.

Peter D. Moore

Peter D. Moore is Senior Lecturer in Plant Sciences at King's College, University of London, UK.

Population ecology

ECOLOGISTS, in seeking to explain the distribution and abundance of organisms, must be versed in a wide range of skills that embrace both theory and observations made in the laboratory and field. As in most other branches of science, they must understand the principles upon which their subject is founded and must know how to collect and analyse useful information. Sometimes this information is further used in the development of mathematical models, and all ecologists should be at least aware of the aims and limitations of modelling in ecology. The complete ecologist's library thus includes works on the principles of population and community ecology, on sampling, statistics and the techniques of analysis. The quartet of books to be reviewed here conveniently spans this range.

There is now an abundance of general textbooks of ecology, which usually encompass much the same material treated in similar ways. *An Introduction to Population Ecology*, by G. Evelyn Hutchinson (Yale University Press: New Haven and London; £12.60) does not fall into this category. It is a personal view of the subject that will delight and stimulate ecologists from the undergraduate level onwards. The principles underlying population growth, mortality, natality, competition and the niche are all presented with masterful clarity as befits one of the founders of modern ecology. But this is no abstract discussion of ecological theory. The wealth of examples from both animals and plants place the emphasis firmly in the real world, and at the same time serve to show how valuable can be the basic tenets of ecology when properly wielded. The flaws lie in what is not included. Predation is as important an ecological process as competition and yet is quite inadequately treated in five pages. As disturbing in an 'introductory' text, is the complete absence of any discussion of dispersal, migration and the general importance of spatial heterogeneity. But what singles this book out more than anything else for me, and will I think endear it most to its readers, is

the mine of historical information that runs parallel with the main text in 388 footnotes. Many of these are just bibliographical references, but others are essays in themselves—such as that on the origins of ideas on territoriality that occupies over two full pages of text, and the delightful cameo portraits of William of Ockham, Malthus, Verhulst and many others. The material in these footnotes is wisely included in the main index which leads to such unlikely entries as "Hortense, Queen", "Josephine, Empress" and "Mussolini, B."

The second book in this quartet, *Guide to the Study of Animal Populations*, by James T. Tanner (University of Tennessee Press: Knoxville; \$8.95), makes a good companion to the first. It deals with the methodology underpinning the study of populations, with chapters on sampling and estimating density, sex and age composition, population growth, mortality and survival. For the first time since 1966 when T. R. E. Southwood's book on *Ecological Methods* first appeared (Methuen; and now extensively revised in a second edition by Chapman and Hall), there is a companion on the same general subject. At about one quarter the length (but only about half the price) and with a very much smaller bibliography, it can be no substitute for Southwood's classic work. It is, however, very clearly written and, by the use of carefully worked examples, presents the analytical techniques such that they may be easily understood and applied. There is for instance a very clear treatment on the derivation of instantaneous birth and death rates and how they may be estimated from data. The book concludes with a useful chapter on the mathematical relationship between population parameters, followed by a short compendium of some different kinds of population model.

A more detailed treatment of mathematical models is to be found in *An Introduction to Systems Analysis: With Ecological Applications*, by John N. R. Jeffers (Edward Arnold: London; hardback £10; paperback £5). This book explains well the objectives of systems analysis and guides the reader through the tangle of terms for

different kinds of model. There are deterministic and stochastic models, descriptive and predictive models, dynamic models, compartment models, matrix models, multivariate models, optimisation models, game theory and catastrophe theory models, all illustrated with particular examples. For a brief flavour of these, I can think of no better text. My main criticisms are aimed at the ten tables with computer listings. These convey little useful information and the space could have been more profitably used.

The final book in this selection, *Statistics*, by D. Freedman, R. Pisani and R. Purves (W. W. Norton: New York; \$13.95, including an *Instructor's Manual*), is a general statistics text, and not aimed especially at biologists. It fits into this quartet only in that a good grounding in statistics is important for any ecologist. The book is intended for "nonstatisticians who want to learn some statistics in order to go about their affairs", and relies on the plentiful use of exercises and a smooth narrative. The authors' have made no

concessions at all to what they call "pluginski", the rather mindless application of a statistical technique to a problem, and have whenever possible banished equations from the text. The result approaches 600 pages of text and notes with an almost complete absence of the different computational recipes needed in the application of everyday statistics. This over-reaction, together with the neglect of any treatment of the Poisson and negative binomial distributions that are so important in ecology, leaves a book ill-suited to the ecologically minded student.

For a concluding remark, I return to Hutchinson's *An Introduction to Population Ecology*. It stands apart from the rest as a work of distinction, that should be studied for its scientific content and savoured for its recondite footnotes.

M. P. Hassell

M. P. Hassell is Reader in Insect Ecology in the Department of Zoology and Applied Entomology at Imperial College, University of London, UK

Sociobiological literature reviewed

THE three books reviewed here all reflect the recent growth in sociobiology. They are, nevertheless, very different in character. *Readings in Sociobiology* and *The Sociobiology Debate*. *Readings on Ethical and Scientific Issues* are collections of reprinted papers (there also are some new articles in the latter volume), while *Sex, Evolution and Behavior* is a new textbook written at a level suitable for first- and second-year undergraduates.

The contrast between the two sets of readings is graphically demonstrated by the fact that only two out of 60 articles in the two are identical: Wynne-Edwards on group selection and Trivers on reciprocal altruism. *Readings in Sociobiology* (Freeman: San Francisco and London; hardback \$18, £9.50; paperback \$9, £4.50), edited by T. H. Clutton-Brock and P. H. Harvey, is aimed at undergraduate or graduate student audiences, and it covers the subject of sociobiology as understood by most academics working in the field. Concepts such as inclusive fitness, evolutionarily stable strategy, parental investment, and cost-benefit ratio crop up on every other page. *The Sociobiology Debate* (Harper and Row: New York and London; \$12.95, £7.95), edited by A. L. Caplan, is largely about the subject as

seen through the eyes of the popular press, politically motivated scientists, and some philosophers of science. Biological determinism, sociobiological theory, pluralism, and Science for the People are phrases which give an idea of its contents.

Both books have their place. The collection edited by Clutton-Brock and Harvey is well chosen and a fair representation of the current state of the field. Important subjects such as altruism, sexual selection, game theory and comparative socioecology are included; and Trivers, Hamilton and Maynard Smith between them wrote half the reprinted papers. There are brief and pithy introductions by the editors to each of the four sections. The collection reflects the bias in the sociobiological literature as a whole towards theory at the expense of data. Only three out of 18 papers are specifically concerned with testing ideas (Bertram on llons, Packer on reciprocal altruism, Clutton-Brock and Harvey on primate socioecology); and no experimental work is included. The book should be useful as an adjunct student text in places where the original journals are not available.

Caplan's book is, I assume, aimed at a different audience, the nature of which is not clear. The papers are in five groups: older writings of T. H. Huxley, Kropotkin and others; 1960s 'human ethology' (for example, Lorenz); philosophers' comments; the biology of sociobiology (Hamilton, and others); and two long sections on the polemics arising out of E. O. Wilson's book. These last two

sections are the core of the collection. There is probably some value in a number of book reviews, short comments, and the Wilson versus Science for the People exchanges collected together; however, the overall result has little coherence. Editorial summaries might have helped, but Caplan's own contributions are sometimes confusing in themselves. This is illustrated by an amusing juxtaposition at the start of the book. E. O. Wilson writes in his Preface "Sociobiology is a discipline, not a particular theory". Two pages later, Caplan starts his introduction by saying of sociobiology "The very boldness of the theory . . .".

M. Daly and M. Wilson's clearly written book (*Sex Evolution and Behavior*; Duxbury Press; North Scituate, Massachusetts) does more to disperse the clouds of confusion, both deliberate and unintentional, about what sociobiologists have said, in particular the little they have said about human behaviour. After a brief introduction to modern ideas about natural selection, the book races through the cost of sex, sexual selection, parental investment, mating systems, life-history strategies, the physiology and ontogeny of sex differences and finally human sexual behaviour. The style of writing is direct and easy to follow; the contents accurate within the constraints of an elementary treatment. A wide range of literature including evolutionary ecology, anthropology, physiology, psychology and sociology is discussed.

Daly and Wilson are strong advocates of the view that sociobiology has a lot to say about human behaviour. Those who think that this is an overenthusiastic standpoint will at least find that Daly and Wilson summarise their ideas with clarity. I quote from their last chapter. In discussing a statement of the Science for the People Sociobiology Study Group they say "Consider the following excerpt from a statement recently signed by thirty-five authors, some of them well-known scientists:

... determinists assert that the possibility of change in social institutions is limited by biological constraints on individuals. But we know of no relevant constraints placed on social processes by human biology. There is no evidence from ethnography, archaeology or history that would enable us to circumscribe the limits of possible human social organisation."

What can this mean? If human gestation, infantile helplessness, language capacity, sensory systems, cognitive abilities, maturational rates, senescence, and so on, are not "relevant constraints placed on social processes by human biology" whatever could be?"

John R. Krebs

John R. Krebs is Lecturer in Zoology at the Edward Grey Institute of Field Ornithology, University of Oxford, UK.

Marine science

An Introduction to Marine Science. By P. S. Meadows and J. I. Campbell. Pp. 176. (Blackie: Glasgow and London, 1978.) Paperback £5.25.

THIS is the latest addition to Blackie's *Tertiary Level Biology* series of textbooks designed for course options at advanced undergraduate level in universities and polytechnics. The word *Introduction* in the title should be interpreted in this context: the book assumes that its readers possess a good biological knowledge and a reasonable background in physical science. Advanced school students, first-year undergraduates and interested non-specialists would find R. V. Tait's *Elements of Marine Ecology* (Butterworths: London, second edition, 1972) an easier and more congenial first book on marine science.

Meadows and Campbell's book covers a wide field, both geographically and scientifically. Consideration of the marine environment ranges from the poles to the tropics and from abyssal depths to mangrove swamps. There is a very short introduction indicating the extent and characteristics of the oceans and of the ecological zones (with their associated biotic communities) that are described in later chapters. This is followed by a description of water circulation and movement, and the more important physical and chemical processes that occur in the sea. Intertidal regions, estuaries, the sea floor and tropical inshore regions are then treated in some detail with respect to geomorphology, ecological significance and interactions between the plants and animals that live there. Collecting gear and methods of investigation are described and illustrated. There is a special chapter on "Productivity, Plankton and the Pelagic Environment" and another on fisheries and farming. A good bibliography has been classified into reference books, popular books, marine review journals, abstracts, and research journals concerned with marine science. There is a comprehensive index with useful cross references.

The style of the book is very terse. A great deal of information has been packed into a short space by making the text and illustrations interdependent rather than complementary; imaginatively conceived diagrammatic presentation of facts and concepts is used to save more lengthy explanations. In consequence both text and illustrations require close attention from the student. Some unwelcome

effects of compression are evident: the book is rather uneven, physiological considerations receive scant attention and some sections—for example, that on fisheries—are too short to give a representative view.

I believe that this textbook will be a valuable adjunct to taught courses in marine science; it will give serious

students a good follow-up to lectures, and guide and encourage further reading. It deserves a place in libraries and on student bookshelves in many countries.

A. B. Bowers

A. B. Bowers is Senior Lecturer in the Department of Marine Biology, University of Liverpool, UK.

Freshwater biology

Biology of Fresh Waters. By P. S. Maitland. (Blackie: Glasgow and London, 1978.) Hardback £11.50; paperback £5.75.

Biology of Fresh Waters is one of a number of titles in a series called *Tertiary Level Biology*, which covers selected areas of biology at advanced undergraduate level. Although designed specifically for course options at this level within universities and polytechnics, the series will be of great value to specialists and research workers in other fields who require a knowledge of the essentials of a subject.

There are few, if any, books dealing with this subject in a comprehensive manner for undergraduates; this book is therefore a welcome addition to the list of available textbooks for biology students. The author has had considerable experience in both teaching and research in this field and has put this to good use in compiling this work.

After dealing with the physical, chemical and biological characteristics of the freshwater environment he introduces the reader to the plant and animal kingdom in a most thorough and concise manner, which is of great value to the student of both biology and ecology. In these days of early specialisation few students get the necessary basic grounding in plant and animal taxonomy and morphology, and the author has appreciated this in providing a 35-page summary on this topic.

Having provided the foundation to the subject Dr Maitland goes on to consider standing and running waters; here, there is inevitable repetition from

chapter 1. In this respect it is difficult to know whether or not the book has necessarily been produced with the chapters in a sequence to avoid repetition and produce a smooth continuity. The remaining chapters are: field studies; adaptation to environment; communities and energy flow; and fresh water and man—all admirable topics but not necessarily introduced to the reader in the right order.

Although freshwater biology has been the subject of many books designed for various levels of readership, quite often the same illustrations appear with a monotonous regularity. It is therefore refreshing to see new, and in some cases original, figures, diagrams and tables, and the author has used some of the results of his own research on the River Endrick and Loch Leven with good effect. The drawings of plants and animals are particularly good but those illustrating various types of equipment are poor (Fig. 5.3, 5.4, and 8.2) and in some cases naive (Fig. 5.15) or unnecessary (Fig. 8.5).

Man's influence on the freshwater environment has been given a wide, though uneven, coverage. Although this subject must necessarily be brief, a few more references to further reading could have been given to the reader who had an interest in any of the subjects covered, which include fish-farming, hydro-electricity, navigation, pollution, recreation and agriculture.

Dr Maitland should be congratulated on producing a very valuable student handbook on freshwater biology which will be of use to students both in the British Isles and abroad.

Derek Mills

Derek Mills is Senior Lecturer in freshwater ecology and fisheries management at the University of Edinburgh, UK.

The complete biologist

EVEN within a course the best teachers do not rigidly adhere to a recommended textbook. Although such bibliolatry would be an anathema, the choice of student texts is an important, even crucial process. What are the criteria?

Factual content, conceptual approach, readability, layout, production and cost rank among the more important. And for the general biology college teacher, the balance is particularly difficult to find. The three books reviewed here cover much of the same ground at a similar academic level; they are all well written; and they are all intended for a primarily American audience (although Hardin

and Bajema tend to use less idiosyncratic field examples, and might therefore be a more acceptable text in the UK). The contents are ordered slightly differently, but the major topics of modern biology (molecular biology, cellular biology, physiology, ethology, ecology, evolution and genetics) form the basis for each text.

The books reflect different underlying philosophies. G. B. Moment and H. B. Habermann in *Mainstreams of Biology* (Williams and Wilkins: Baltimore) believe that an historical perspective gives "a lasting sense of biology as an ongoing human enterprise", but they've gone overboard. No student should be expected to wade through the names of eight or ten scientists (and their institutions) on a page of text. Similarly, the book is liberally illustrated by photographs of the illustrious. (It's true, I didn't know that Lynn Margulis wearing dark glasses and a headscarf bore an uncanny resemblance to Greta Garbo.) B. T. Scheer, in *Patterns of Life* (Harper's College Press: New York and London) is, if anything, prone to the other extreme. He is clearly a good, experienced teacher who knows how to communicate to his students, but his book lacks lustre in both conception and production. The dedicated student might do well with the somewhat stodgy approach. The average student would not. In Scheer's defence, however, goal questions are effectively set at the beginning of each chapter and brief introductions at the start of each of the six sections aid in a sense of achievement. G. Hardin and C. Bajema chart a good middle ground in *Biology: Its Principles and Implications* (Freeman: San Francisco). Their book is excitingly written, clearly and liberally illustrated and beautifully produced. They have thought hard and well about this new edition, and Bajema's academic qualities (of which more later) make a welcome complement to Hardin's hard-hitting evangelism.

But what of content? Perhaps this is best treated at two levels. First, the balance that the authors give to the various components of biology. Second, the extent to which they are in touch with new ideas and research, and have the ability to integrate them into a student text. Ignoring the books' excesses for the moment, I found Scheer extremely weak on molecular biology. It is hardly integrated into the text, but almost totally confined to an Appendix entitled "The Chemical Explanation". That's not good enough and, as a consequence, topics such as photosynthesis, hormone action and nutrition are very poorly dealt with. Similarly, Hardin and Bajema are relatively weak on molecular and hormonal biology. Perhaps because they want to excite their audience, they gloss over some of the things students ought to learn—straight ethology, for example. If

students are going to progress beyond the level at which these books are aimed, or if they are going to develop an amateur interest in Natural History, then taxonomy will be of importance. It is here that two of the three texts are inadequate. Moment and Habermann barely mention the topic, whereas I found Hardin and Bajema's treatment over-technical and unexciting. I know that taxonomy is not usually exciting, but Scheer makes a valiant (90-page) attempt with a clear phylogenetic exposition. He deserves credit. The books each had so much ground to cover that they rarely deal with topics in excess, though Hardin, not surprisingly, is one for the eco-crisis.

These books are generally up-to-date, using new material which has been largely condensed from specialist sources. It is here that Hardin and Bajema come right to the fore. Not only have they assimilated current research from each area that they cover, but (within my own specialities at least) they have also managed to describe the more exciting and potentially important findings. At the

end of each chapter, they refer to *Scientific American* offprints and other easily conceptually accessible readings. And they haven't missed the human angle. In "boxes" scattered through the text are reprints of short, classic papers from Darwin to Watson and Crick (including, of course, *The Tragedy of the Commons*—but that's excusable), asides on concept and method, and even political analyses. This text, alone among the three, is integrated at almost every level, has set problems (some of which are tersely answered at the back) and is a mine of accurate well-presented information. With the few reservations outlined above, I commend it for serious consideration even by those who already have a favourite text. Everyone, like me, will learn something new from the book.

Paul Harvey

Paul Harvey is a Lecturer in Biology at the University of Sussex, and currently a visiting faculty member in Biology and Anthropology at Harvard University, Cambridge, Massachusetts.

Comparative physiology

In *The Vertebrates: Their Forms and Functions* (Charles C Thomas: Springfield, Illinois; \$15), C. G. Crispin attempts to survey the whole of vertebrate zoology. Unfortunately, by the time he has covered histology and phylogeny in outline, and named and subdivided the skeletal, muscular, lymphoid, nervous, integumentary, respiratory, digestive, excretory, reproductive and endocrine systems he has virtually no space left actually to describe them, let alone discuss their functions. There is little to be said in favour of this relatively expensive book and it is hard to see for whom it could be useful. The blurb on the cover refers to it as "an alternative approach to contemporary vertebrate zoology" and so it is, by being about 50 years out of date. It is the worst sort of students' cramming book, giving more emphasis to artificial subdivisions and their names than to functional significance, and one can imagine them learning by heart the three names of the methods of tooth attachment to the jaw in order to pass a multiple-choice test. In spite of lip-service paid to function it is essentially morphological in outlook and leaves the reader with a false sense of what should be a living and exciting

subject. It is out of tune with modern ideas and contains just the sort of factual information best calculated to put advanced school biologists off their subject (and it is too elementary for any later course).

Older British readers should not be put off by the slangy title of *Mammalogy* (W. B. Saunders. Philadelphia and London; £12) by T. A. Vaughan, as it can be thoroughly recommended as a very satisfactory reference book for second- or third-year undergraduate zoologists onwards. Probably nowadays few university courses are so specialised on mammals that it could be a major required textbook, but for any course specialising in vertebrates it would be one of the first books in the library to refer a student to when a question arose concerning mammals.

After a brief description of mammalian characteristics, the evolution of mammals from the mammal-like reptiles is surveyed. The whole complex story of the therapsid radiation cannot be told, but sufficient description (including diagrams) of key types such as *Cynognathus* is provided to give a fair account. The remainder of the first half of the book deals with the various orders in turn, giving detail to family level, and stressing ways of life as well as standard morphological detail. On the whole, the less well known groups are described more fully.

Chapman & Hall

Associated Book Publishers Limited,
11 New Fetter Lane, London EC4P 4EE.

PRINCIPLES OF APPLIED GEOPHYSICS

Third Edition

D. S. PARASNIS

Geophysical methods form an integral part of the search for metallic ores, industrial minerals and the raw materials of energy such as oil and uranium. As these become increasingly scarce, applied geophysics acquires a greater importance in the search for new deposits. This new edition provides a concise but comprehensive survey of both the theoretical and practical aspects of modern geophysical methods and contains topics not found in current texts, including the Kernel function theory of resistivity sounding interpretation, Dar Zarrouk curves, and radioactive density measurement.

FLAMES

THEIR STRUCTURE,
RADIATION AND
TEMPERATURE

Fourth Edition

A. G. GAYDON, F.R.S. and
H. G. WOLFARD

This thoroughly revised edition deals with the physical techniques used to study the structure and temperature distribution of flames – from simple bunsen and candle flames to complex gas turbine and rocket engine types. The book now includes modern aspects such as the new techniques of laser-Doppler anemometry and laser-Raman spectroscopy for temperature measurement and recent ideas on the processes of soot formation.

Hb 0 412 15390 4 £18.00

INTRODUCTORY BIOPHYSICS

F. R. HALLETT, R. H. STINSON
and P. A. SPEIGHT

An introductory textbook for students of biology, agriculture and physical science, which demonstrates the need to approach certain biological problems from a physical point of view. Heavy emphasis is placed on problem solving, but the level of mathematical sophistication is deliberately kept low.

1978 256 pages

Pb 0 412 21680 9 £5.95

TAXIS AND BEHAVIOR

*Receptors and Recognition
Series B. Volume 5*

Edited by G. L. HAZELBAUER

Sensitivity and response to changes in the environment is basic to living organisms. Taxis – directed movement in response to environmental alterations is widespread and is often the basis of elementary behavior patterns. In this volume, the phenomenon of taxis is reviewed against the background of seven different living systems, bacteria *Paramecium*, slime molds, nematodes, plants, insects and mammalian leucocytes, each a focal point of active research.

RECEPTORS AND RECOGNITION

SERIES A VOLUME 6
INDEX VOLUME

Edited by P. CUATRECASAS and
M. F. GREAVES

The publication of Volume 6 in Series A marks the conclusion of the first phase of Chapman and Hall's coverage of this important and growing area of biological and medical science. The six A Series volumes provide a comprehensive overview of studies in this field written by internationally known experts. Volume 6 contains extensive author and subject indexes covering material in Volumes 1-6.

INTRODUCTION TO MAGNETIC RESONANCE

A. CARRINGTON, F.R.S. and
A. D. McLACHLAN

Designed primarily for first year graduate and advanced undergraduate students of chemistry. The aim has been to present the most important principles and applications of the two kinds of magnetic resonance: nuclear magnetic resonance (N.M.R.) and electron spin resonance (E.S.R.), both of which depend upon the same fundamental principles. Difficult points are not evaded although theory is presented as simply as possible.

from **COLLIER MACMILLAN LTD**

and in particular that miscellaneous collection of animals masquerading as the order Insectivora is introduced in masterly fashion. There are photographs of members of nearly every family and clear drawings of skulls, teeth, limbs and other skeletal details as appropriate, all portrayed in a clear, uniform style similar to that first adopted in Romer's *Vertebrate Palaeontology*.

The second half of the book is devoted to a number of topics of general biological interest which have special relevance to mammals: ecology, zoogeography, behaviour (especially social behaviour), reproduction, metabolism and temperature regulation and echolocation, with a final brief comment on the effects of man on mammalian wild life. From this list it can be seen that only certain subjects are included, but many of them are of obvious importance like the section on zoogeography. This covers a summary of types found in the various regions, a description of continental drift and its effects including a very useful discussion of the "unusual" faunas, past and present, of South America, Australia and Madagascar. Other sections like that on echolocation in bats and cetaceans provide concise summaries of detailed topics which presumably reflect the author's interests.

It is very easy to read large sections of the book straight through, as well as to use it as a reference book for facts, ideas and as a lead in to further reading. It is well produced and relatively cheap—in fact a good buy.

At first sight one might suppose that *Animal Physiology*, by Roger Eckert and David Randall (Freeman: San Francisco and London; \$19.95, £12.95), is merely another in the series of comparative physiology texts which started with Prosser's and which has been added to at the rate of about one every four years ever since. And so in many ways it is, for much of the content is in common with the latest editions of its rivals. But this attempt does the standard job well, and has many advantages and few disadvantages when its special emphasis is identified. The book starts with basic concepts of physics and chemistry (for example, Ohm's Law and osmosis), works through cellular processes such as the electron transport chain, active transport and membrane potentials, and then covers individual nerve and synaptic functioning. This leads on to sense organs and the principles of central nervous integration, then to the other systems: muscle, cilia and flagella, chemical messengers, osmoregulation and excretion, blood circulation and gas exchange. There are appen-

dices containing useful formulae (though kinetic energy should not be printed as $1/2mv^2$) and a glossary.

The main theme of the book is the explanation of physiological processes and their control; it is not a survey of comparative physiology. The choice of which processes are to be described and explained is rather selective, but mammalian functions are in general fully covered (apart from digestion and temperature regulation) and so are the major variants and additions that occur in other vertebrates and in some invertebrates, for example, osmoregulation and circulatory systems.

In spite of the complexity of the subject the book is readable. Within its chosen limits, it is an excellent textbook, clearly most appropriate for second- and third-year undergraduates taking courses in comparative or in mammalian physiology. It highlights the fact that so many processes in physiology now have their explanations pushed back to more molecular levels than they did 10 years ago. The reader

of this book might be forgiven for thinking that there is little more to be found out, so complete and satisfying are so many of the descriptions given. Rightly, in the cause of clarity, the text contains only sparing use of "probably" or "as far as is known at present" and the topics described tend to be those for which an explanation has been suggested in the literature. So it is the sort of textbook which reinforces and extends a lecture course, rather than taking its place, and it is essentially aimed at helping students understand how animals work. It is intentionally not a reference book, but the references which are given should be quite enough to allow a student (or a lecturer for that matter) to use it as the start of a more detailed library search on any specific topic.

R. W. Murray

R. W. Murray is Senior Lecturer in Zoology and Comparative Physiology at the University of Birmingham, UK.

Fundamental nutrition

Fundamentals of Nutrition. Second edition. By L. E. Lloyd, B. E. McDonald and E. W. Crampton. Pp. 466. (Freeman: San Francisco, 1978.) \$19.50.

THE title of this book gives a very good indication of its contents and the intended readership. Each chapter is short so as not to overface the first-year undergraduate or college student, and at appropriate points boxes are inserted with topical information such as breeding cereals for high lysine. Potted biographies of eminent nutritionists also add to the readability of the main text.

Introductory chapters describing the composition of foods and animal tissues are followed by sections on energy and protein, vitamins and minerals; the latter, sensibly, not illustrated by well-used photographs of animals suffering from various deficiencies or excesses. Photographs could, however, have been usefully added to illustrate some of the more complex methods which are well described in the text.

A further group of chapters includes, refreshingly, discussions on experimental design and analysis and descriptions of the major areas of animal experimentation in nutrition, although

many students would presumably be taking a biometry course in parallel with nutrition and would be referred to a more detailed and comprehensive text in that subject. The same might be said of some of the biochemical coverage; surely no modern nutritionist can escape without at least one full course in biochemistry which would render superfluous those areas dealt with in this book.

The last five chapters, occupying almost 100 pages, deal admirably with quantitative aspects of nutrition—how much of each of the previously defined nutrients are required daily by various species, including man, in various physiological states. This is not to imply that the book is a practical feeding manual, and those examples of farm animal feeding that are given are based on American standards which are not relevant to a large part of the world. The use of the calorie rather than the internationally agreed joule as the unit of energy adds further possible confusion for the majority of students who are now familiar with the latter. There is a useful index.

This is a comprehensive coverage of the whole subject of nutrition and is written in a manner that will be appreciated by all who are tackling this subject for the first time.

J. Michael Forbes

J. Michael Forbes is Lecturer in Animal Physiology and Nutrition at the University of Leeds, UK.

Plant pathology

THE approach of *Fundamentals of Plant-Pest Control*, by D. A. Roberts (Freeman, San Francisco and London; \$17.50; £10.20) is to try to unify all aspects of plant pest control, pointing out common features as much as possible, and culminating in the necessity for the systems approach in order to achieve integrated pest control. This is a theme of much recent thought on the subject and it is evidently right that undergraduates should study and evaluate the approach.

After a general introduction to the plant-pest ecosystem, a series of chapters reviews the structure and functioning of crop plants, followed by the dynamics of plant pest populations and the basic elements of plant pest control. The second main section reviews different types of pests, in the wide sense: microbial pathogens, nematodes, arthropods, weeds and vertebrates. Finally, the systems approach is outlined and the author concludes with his reflections on pest control in the future.

Desirable though the ultimate objective may be, one is left somewhat dissatisfied with the book as a student text and not altogether convinced by the arguments as they stand. There is an unsatisfactory discrepancy between the potential readership of the book and the background knowledge one would expect of the reader. If it is intended for the naive reader, who has not studied plant pests in the more traditional way, then it is hard to see how he can properly evaluate the whole of the argument or cope with the use of terms like mycoplasma-like organisms or /2-chloro-4-(ethyl-amino)-6-(isopropylamino)-s-triazine/. If, on the other hand, the reader has the background, then why does he have to be given a diagram showing an elementary view of plant structure, be told that organic compounds contain carbon, or study a table setting out among more appropriate things the type of metamorphosis in stoneflies, book-lice and fleas. Such a book must surely aim to refine the understanding of a student with an adequate background, and in this sense more than a third of the text is rather unnecessary.

Leaving this aside, the sections on each type of plant pest are well structured accounts of the application of basic principles to each case. These chapters, contributed by different specialists working consistently to the author's theme, are, with the exposition of population dynamics and the

basic elements of control in the first section, the strongest section of the book. The plant pathology, entomology or weed biology student, in a context where such people are still separate, as is largely the case in the UK, will most profitably read the chapters which do not relate directly to him. The unifying approach cannot, however, always accommodate the real situation altogether. There is ultimately not so much in common between vertebrate pest control and that of nematodes as there is between the latter and plant disease control. The concepts of vertical and horizontal resistance arising from van der Plank's view of plant pathology and applying to races of host-specific pathogens and varieties of their hosts transpose rather superficially to the interactions between plant and insect species. Nevertheless, detailed differences should not submerge the most important fundamental similarities.

The systems approach of the last section is illustrated by the system "undergraduate education in crop-plant-pest control". Why, one wonders, is it not possible to illustrate it by a real plant protection system? The latter only appears in a highly condensed account of computer models such as EPIDEM. One can accept the validity of computer modelling or integrated pest control as such, but this text does not altogether convince one of the real, productive, value of the "higher systems level", or systems approach itself. Undergraduates may profitably

read this text but should keep their feet firmly on the ground and their critical faculties well in trim.

G. N. Agrios' *Plant Pathology* (Academic: New York and London, \$22.95) was in its first edition a textbook one was only too glad to recommend to students. It was invaluable for its thorough and clearly expressed accounts of selected diseases, for its abundant and excellent illustrations and life-cycle diagrams, and for the confidence with which one could advise students to refer to it as a supplement to lecture courses. It had its faults: the introductory chapters on general concepts were rather solid catalogues of information, without much feel for the essentially research orientation of subjects such as biochemical defence mechanisms; the rather limited number of diseases treated was often a problem, especially for the European user.

This new edition triumphantly corrects the latter fault, and is generally revised and brought up to date. The introductory chapters have been somewhat polished and some superfluous material has been removed. There is no doubt that this new edition is even better than the first and it can be thoroughly recommended as an invaluable teaching aid with very few reservations.

I. M. Smith

I. M. Smith is Deputy Director of the European and Mediterranean Plant Protection Organization in Paris

Plant anatomy

THE first edition of *Plant Anatomy* (Part I: Cells and Tissues) by E. G. Cutter, was published in 1969 and contained 168 pages. Now, almost ten years later (Edward Arnold: London; hardback £13.50; paperback £6.75), the 315 pages contain considerably revised and updated information while retaining the essential character of the original volume. Considerable use has been made of both scanning and transmission electron micrographs and, in general, the reproduction of these is quite respectable considering the quality of paper and method of printing. It is good to see such comprehensive revision—to the extent that transfer cells warrant a whole new chapter of their own—but it is a pity to find that some other cell types (for example, endodermis and hypodermis) are relatively very neglected. To some

extent this arises because this book is a companion to the second part (Organs) in which the endodermis, for example, is more fully described. Nevertheless, it is regrettable that while, as written in the review of the first edition (*Nature*, 222, 1100; 1969), "No cell types are omitted . . .", the degree of coverage is so variable.

This is very much a plant anatomy book with a difference: constantly probing and questioning and never very far away from the functions of the cells and tissues being described. Thus, the author is not satisfied simply to classify or to catalogue but attempts to show how the specific structures serve their different roles. Glands, and other cells and tissues, are no longer viewed simply as interesting structural aggregates but also as morphological entities that are uniquely adapted to serve their (described) function. Moreover, mature cells are not assumed to appear *de novo* and Dr Cutter takes pains to stress the subject of differentiation, both in a specific chapter where genetic control, totipotency,

polarity, pattern formation and nuclear-cytoplasmic interactions are briefly reviewed and also at appropriate times in the other chapters. This style leads to a book that is very readable and well suited to elementary students as well as to the more experienced botanists who will undoubtedly benefit from it.

Cell contents and cell walls are despatched briefly but efficiently in consecutive chapters. All the major organelles are reviewed in up-to-date fashion. It is good to see the most recent views on, for example, C_4 chloroplasts and plasmodesmata, although we might have hoped for a more comprehensive assessment of the structure and role of microtubules than the dozen lines allowed for them. Indeed, the whole area of membrane structure and techniques such as freeze-etching is ignored, as is the work on cell wall formation by, for example, Willison and Brown. This is surprising and disappointing in a book that tries to relate structure to function as membranes are of such paramount importance.

It would have been much more useful if the subject coverage in this book had been more evenly distributed. However, taken as a whole, this is an attractive volume that should encourage botanists to think more about how the structure and function of plants are intimately inter-related. Anything that does this is to be welcomed and Dr Cutter has made a notable step in the right direction.

Applied Plant Anatomy (Longman: London and New York, £4.95), by D. F. Cutler, seeks to illustrate the way that a sound knowledge of plant anatomy can be applied to the solution of many important every day problems. It is good, in a textbook of plant anatomy, to see pictures such as that of a papyrus sandal and to read about "wood in archaeology": this does help the subject to come alive. This novel approach leads to a book that is different from most others on elementary plant anatomy and one that is both readable and enjoyable for even the newest student of botany.

The introductory chapter contains brief notes on techniques for both light and electron microscopy. This is followed by chapters on the basic morphology of plants; a good, simple, illustrated glossary, the histology of plant organs; meristems; vascular tissues; adaptive features; flower and fruit; and economic aspects of applied plant anatomy. Each chapter is well illustrated by clear line diagrams and micrographs. The distribution of micrographs is a little uneven and, indeed, there might have been more of them altogether. At the end of each chapter there is a small list of suggested further

reading and, where appropriate, lists indicating where to look to find particular anatomical characters. This is a most valuable addition and covers plants worldwide. The further reading lists are rather too short and often quite dated. Having commented on the usefulness of electron microscopy to the study of plant anatomy, the author then fails to cite a single further reference in this area. Indeed, the four books suggested at the end of chapter one serve as a rather limited coverage of the subject area.

The introductory chapter on techniques is useful but it is a pity that

some of the figures concerning the resolution of microscopes seem to have been muddled: both TEM and SEM resolution are out by a factor of 100! The index is concise and helpful and, indeed, reflects the whole tone of the book, which is to convey a very considerable amount of information in a palatable and easily understandable style.

A. W. Robards

A. W. Robards is Senior Lecturer and Head of the Electron Microscope Laboratory in the Department of Biology at the University of York, UK.

Principles of plant nutrition

Principles of Plant Nutrition. By K. Mengel and E. A. Kirkby. Pp. 593. (International Potash Institute: PO Box 41, CH-3048 Worblaufen-Bern, Switzerland, 1978.)

This book is broadly based in accordance with the implications of its title and achieves a commendable integration of soil and plant aspects of nutrition. The partnership of geographically separated authors, who are both practically orientated university teachers, provides a background of wide experience and as shown by the principal bibliography (about 1,400 references) an extensive familiarity with the subject.

Chapters 1 to 6 (totalling 290 pages) describe some general principles. Considerable attention is given to plant-soil relationships; nutrient uptake, translocation and storage; nutrient availability in relation to crop needs; general effects of nutrient deficiencies; and methods of nutrient application and correction. A number of major physiological activities—photosynthesis, nitrogen fixation, nitrogen assimilation, water relations, active transport, nutrient absorption—are described in sufficient depth to provide the necessary background for understanding the role of various elements, although respiration seems less adequately considered.

Chapters 11 to 18 deal separately with each of the familiar essential elements—except chlorine, which is reviewed in three pages in a chapter confined to some possibly beneficial or indirectly essential elements: cobalt, silicon and vanadium. Reviews on separate elements cover soil aspects of their availability, their metabolic roles and deficiency and some toxicity effects on growth. These chapters provide a good general idea of the importance of the elements. These and the other chapters are each concluded with a general reading list to supplement

the numerous specific citations in the text.

Chapter 19 concludes the treatise with examples of several toxic or less familiar elements which are discussed in more general terms and it includes several interesting miscellaneous reports. There are a few minor omissions—for example, regarding the production by certain plants of apparently specific citrate and oxalate metal complexes especially with nickel and chromium; the quite extensive work on tungsten relegated here to a few words on page 149 on tungsten inactivation of nitrate reductase by unspecified means; the original, rigorous and model investigations of Brownell on the absolute need for sodium by *Atriplex vesicaria* (though his later discovery of its possibly general importance in C_4 -type photosynthesis plants is nevertheless noted); the differentiation of apparently two types of malate enzyme; the exciting conclusions of Meish *et al.* regarding the essential role of vanadium in green algae, thought to involve the formation of delta aminolaevulinic acid (though this news may have 'broken' as the book went to press); and finally (though possibly again just too late), the further work of Polacco on the need for nickel in urea metabolism since the first report on urease by Dixon *et al.* briefly cited on page 514.

This quite comprehensive and well documented book will be of value to students and lecturers alike in faculties of agricultural science, botany and biological sciences and should also be welcome in the libraries of agricultural institutes, advisory workers and consultants. It is especially commended for its relevance to practical aspects of crop nutrition and for proper appreciation of the general principles on which practice should be based.

E. J. Hewitt

E. J. Hewitt is Head of the Plant Physiology and Biochemistry Section at Long Ashton Research Station, and Reader in Plant Physiology at the University of Bristol, UK.

Plant taxonomy

Essays in Plant Taxonomy. Edited by H. E. Street. Pp. 304. (Academic: London, New York and San Francisco, 1978.) £12.50; \$24.50.

PROFESSOR Tom Tutin has no rival for the title of *doyen* of British plant taxonomists, and few would question the appropriateness of this *Festschrift* on the occasion of his seventieth birthday, which so nearly coincided with the completion of *Flora Europaea*, his second *magnum opus*. We must here, however, examine the book, not from the standpoint of an admiring friend, but of a student asking what use it will be to him. Symposia are at present, perhaps, an over-popular form of publication: in many of them the thread of supposed common interest which binds the essays together is far too tenuous, and indeed, in the case of some complimentary volumes such as this, completely non-existent. The present work, however, is free from this reproach, for all but one of the essays are relevant to taxonomy on the strictest definition. The editor, who unfortunately did not live to see his work in print, planned the volume well, but part of the credit for its efficient and speedy production must go to Dr C. A. Stace, whose share was greater than his modesty permits him to disclose.

Four of the essays are wide-ranging reviews with no special claim to an original interpretation, and these are the parts of the book which will be of most value alike to the general student and for those who are specialising in taxonomy. Valentine on ecology, Smith on chemistry and Moore on chromosomes, all considered in relation to taxonomy, give judicious summaries of their themes, with well chosen and up-to-date bibliographies; and Richards on the taxonomy of bryophytes gives an excellent account of a field to which most angiosperm taxonomists are complete strangers. Stace on breeding systems and their taxonomic implications also covers a wide field, but with a more individual approach; he ends with a justified *cri de coeur* for a less Procrustean system of infraspecific categories than that laid down by the International Code, but the genius who can produce a system which is at once flexible, unambiguous and reasonably simple has not yet been found.

Somewhat more specialised, but still in the nature of reviews and thus of value to students whose interests lie in the fields concerned, are the essays by

Hawkesworth, who introduces the reader to the peculiar and complex problems posed by the taxonomy of lichens and their fungal constituents; Parker on taxonomic problems in crop plants; and Hawkes on the related theme of conservation of genetic diversity, especially in plants of economic interest.

Cook on the *Hippuris* syndrome (the frequency in aquatic plants of very diverse families of a vegetative structure superficially similar to that of *Hippuris*) belongs rather to the realms of morphogenesis and evolution than taxonomy, but it should generate some constructive head-scratching of benefit even to the elementary student.

Yeo attempts to explain why *Euphrasia*, in spite of a normal breeding system, presents taxonomic problems as intractable as those of many apomictic or autogamous genera. To the reviewer his effort must be classed

as a gallant failure, but the essay is essential reading for anybody working on semiparasitic Scrophulariaceae. The remaining essays (Walters and Richardson on different aspects of endemism, Sneath and Chater on a rather esoteric analysis of dichotomous keys, and Heywood on past and future Flora-writing) are also of interest mainly to the research-worker or teacher.

Almost without exception the essays have a lucid and readable quality which sets them apart from the contents of most biological journals. The book should be dipped into by all honours students of botany. Those whose interests lie mainly in fields close to taxonomy should read most of it carefully and chase up some of the clues given in the excellent bibliographies.

D. A. Webb

D. A. Webb is Professor of Systematic Botany at Trinity College, Dublin.

Pollen analysis illustrated

An Illustrated Guide to Pollen Analysis. By P. D. Moore and J. A. Webb. Pp. 133. (Hodder and Stoughton: London, 1978.) Hardback £8.50; paperback £4.95.

THE authors have produced this book, intended for undergraduates and advanced school students, as a laboratory manual. They hope that it will be used as a supplement to Pennington's *History of British Vegetation*. The book is a guide to pollen-bearing Quaternary deposits, the collection and treatment of samples, pollen morphology, the identification of pollen, the practice of pollen counting and interpretation of results.

Chapter 5 (Pollen and Spore Key with Glossary) will, I am sure, be much used by pollen analysts whether beginners (from school to postgraduate) or established workers. The authors rightly stress more than once the need for a reference collection to corroborate identification made from the key and illustrations. In its liberal supply of plates, including stereoscans, of pollen grains and spores the chapter contrasts strongly and favourably with Faegri and Iversen's famous textbook (*Textbook of Pollen Analysis*) in which the keys are discouraging in their lack of

illustration. The beautifully illustrated, two volume *An Introduction to a Scandinavian Pollen Flora* by Erdtman *et al.* is not easy to come by and is expensive, as are other pollen atlases.

The accounts of important modern developments such as absolute counting, statistical treatments, computing and zonation, are lucid and level-headed, with the right balance of the need for greater objectivity and credit for the many successes of the more traditional methods.

The plates and figures are well executed and appropriate but a reader with little archaeological knowledge could be misled, if temporarily, by Fig. 1.1 which shows the sequence of archaeological periods but gives no indication of timespans. Also I wonder what a beginner will make of the description and drawings (Fig. 3.1 (b)) of the Russian borer, redrawn inaccurately from West's *Pleistocene Geology and Biology*? He may well be puzzled. Perhaps the Mackereth corer, an important though elaborate tool in palaeolimnology, deserves a little more detailed treatment, though few readers will have the chance to use or even see one.

However, these are small points, detracting little or nothing from this valuable, readable book which will be used freely and successfully in the ways the authors intend.

J. H. Dickson

J. W. Dickson is Lecturer in Botany at the University of Glasgow, UK.

Present state of academic psychology

Psychology Survey. No. 1. Edited by B. M. Foss. Pp. 220. (George Allen and Unwin: London, 1978.) Hardback £5.50; paperback £2.50.

WHAT is the perfect introductory text for psychology students? The selection pressures of the market should by now have weeded out the unfit, and we ought to be approaching a form well adapted to the British students' needs. The American form, with its pictures and snippets of information, seems fairly stable, but the comprehensiveness of such products at a shallow level is unsuitable for most British introductory courses. Usually our lectures and tutorials are not part of a single planned course, and tutors, left to devise their own essay titles, naturally look out for up-to-date surveys of currently fashionable topics. The *Annual Review of Psychology* is too heavy and unselective, and the professional review articles, such as those published in *Psychological Bulletin*, involve too drastic a plunge in at the deep end.

It is not surprising, therefore, that there is a market for books of introductory reviews. Early examples were the present editor's *New Horizons in Psychology* (at slightly too elementary a level) and the *British Medical Bulletin's Experimental Psychology* of 1964, followed in 1971 by *Cognitive Psychology*. Recently several publishers have issued series of short paperbacks, each on a special topic within psychology, but these have been uneven in standard; and buying even half a set would be expensive. In the book under review, we have the beginning of what may prove an ideal solution. It is the first of an annual volume of reviews, designed, judging from the contents, to throw the student in just out of his depth. It is, therefore, for the beginner who can rely on personal guidance if necessary, and not for someone setting out on his or her own. Each year, to keep the series fresh, there will be a new editor; and providing we can be kept up to date by suitable recycling of topics, the enterprise deserves to be very successful.

In this volume there are 14 chapters of about 15 pages, each by a different author who is a well known specialist in his field. The titles, in order, are, Visual Selective Attention, Verbal Remembering, Conditioning, Mental Imagery, Psychophysiology, Cognitive Effects of Cortical Lesions, Experimental Child Psychology, Sex Differences, Behaviour Modification, Human

Learning, Cross-Cultural Studies, The Bases of Fluent Reading, Occupational Psychology, and Environmental Psychology. There is thus a gradual shift from the 'core' subjects, highly organised areas currently under tough minded experimental scrutiny, to applied areas of research. In core subjects the reviewer's problem (generally solved remarkably well) is to get across, in a brief and simple form, the involved theories that make sense of the experimental work and that mark the boundaries of the area. Applied areas, on the other hand, are bounded by the set of practical problems that define them, and within such an area different approaches are possible; the result is diffuse, and short reviews inevitably seem selective and sketchy. In all cases,

however, the student is given a start, and a useful list of references.

The reader is left to work out the thread that holds the chapters together. Michael Eysenck, author of *Human Memory*, finds encouragement in "the emergence of general theories that have considerable application outside the limitation of a specific experimental task", but there is not much sign of this in the book and one feels by the end that the areas of psychology, like games, share no more than a family resemblance. That, no doubt, accurately reflects the present state of academic psychology.

A. W. Still is Lecturer in Psychology at the University of Durham, UK.

Physiological psychology

A NOTABLE feature of this set of books on the central nervous system and behaviour is that each is written by one author, an unusual and welcome event now that so many books consist of collections of previously published papers, accounts of conference proceedings, or chapters by writers whose only common link is an editor. A single author can avoid the well known problems of multi-author works—repetition, abrupt change of style, and the difficulty in developing a point of view by sustained argument. The advantages of going it alone certainly show in the present selection, albeit to different extents. In *A Primer of Psychophysiology* (Freeman: San Francisco and Reading; hardback £8.90, paperback £4.40), James Hasset presents a brief, clear and bouncy account of an approach to behaviour that is neglected in most British psychology departments. What is psychophysiology? After rejecting definitions that simply refer to the methods used by psychophysicists, for example, recording the EEG, he settles for "a strategy for studying human behaviour and experience". Now many will argue that the strategy is no more than a reflection of the methods used, and the bulk of the book is certainly devoted to a straightforward description—whose usefulness should not be underestimated—of such things as the electrical properties of the skin, respiration, cardiovascular states, pupillary changes, muscle tone, eye movements, and the gross electrical activity of the brain, together with detailed accounts of how to measure

them. It is undeniable that the measurements correlate well with psychological states such as fear, tension, anger, curiosity, embarrassment, arousal, and habituation, to name only a few, but the reader who is looking for some mechanistic or conceptual explanation of our behaviour will be dissatisfied. Psychophysiology may have useful applications, for example, in the therapeutic use of biofeedback or revealing individual differences and psychiatric conditions, but the book does not show whether it has explained anything important.

On the Texture of Brains (Springer: Berlin; DM16.30, \$7.50), by V. Braitenberg, is equally slim, but there the resemblance ends. It is a collection of eight short essays whose collective message is that "the structure of brains is information about the world", by which the author means not that we can understand the world from brain structure but that the structure of the brain has to reflect certain features of the world in order for the organism to deal with its spatial environment. It is an attempt to understand behaviour in terms of neuroanatomy. A crucial point is that not all levels of anatomical analysis are equally informative. To understand a brain by gross dissection is like trying to understand a text by dividing it into chapters; to analyse it by studying the structure of individual cells is about as helpful as examining prose in terms of the letters of the alphabet. The right approach, it is maintained, is to study how cells are connected. By so doing we find that the basic design is remarkably similar from insects to man. Complexity and variety of behaviour are therefore a product of the total number of cells and their interconnections, rather like the dif-

ference between a short poem and a long novel. It also follows that the general principles of how nerve cells control behaviour may be studied in organisms much simpler than ourselves, which explains why so much of the book is devoted to the author's own leading role in successfully demonstrating how visually guided navigation in flies can be explained by the fibre connections in the eyes and visual ganglia. Now this approach has undoubtedly been fruitful with insects, and promises to be so with the mammalian cerebellum, but major problems arise in considering the cerebral cortex, where input-output relationships fail to reveal what lies between them. It is unclear how learning, memory and prediction are to be dealt with in general terms except by old and loosely formulated notions like cell assemblies, changing patterns of excitation, and internally activated representations that are matched against sensory patterns. How these arise is not explained. And it is easy to see how a slight mistake can lead to serious misconceptions. To take one of many examples, it is stated that the principle of equipotentiality, by which it matters not a jot which part of the cerebral cortex is removed, demonstrates that regional specialisation does not occur. This results in a needless struggle to explain something, for we now know that the principle does not follow from the experiments on which it was based. Nevertheless, Braitenberg has written a joyous, learned and provocative book that makes the reader think at every turn.

Developmental Neurobiology (second edition, Plenum: New York and London), by M. Jacobson, and *Developmental Plasticity of the Brain* (Oxford University Press: Oxford, £4.95), by R. D. Lund, cover similar ground. Both deal with the ontogeny of the nervous system, the differentiation of nerve cells and interactions between them, and the mechanism of neuronal specificity. Apart from price there is not a lot to choose between them, but Jacobson is slightly more detailed and comprehensive, deals more effectively with the neuromuscular system, provides a succinct but excellent account of the extensive work on the retinotectal map in amphibia, and is more lavishly illustrated. Lund is more thorough on environmental influences on central connections and his method of imparting information by asking a question then answering it, instead of simply presenting facts, is helpful, as are his concise summaries at the end of each chapter. If either book lacks anything it is an account of work with invertebrates and some recognition of the importance of behavioural experi-

ments done in conjunction with developmental experiments. But these are slight criticisms of two scholarly works that will be deservedly popular. Their main rival is *The Formation of Nerve Connections* (Academic: London) by R. M. Gaze, which is now several years out of date.

Brain Systems and Psychological Concepts (Wiley: Chichester, UK; £12.50), by J. Boddy, is an undergraduate textbook of physiological psychology, and it is useful to know how it differs from those of similar length and subject matter by Milner, by Thompson, and by Grossman. The overlap with all of them is huge, particularly in describing the sensory pathways, hunger, thirst, sex, emotion, brain stimulation, sleep, memory, and research techniques. However, there is much more emphasis in Boddy's book on the relevance of experiments on human subjects, for example, in considering information processing, and the chapters on mental illness and the effects of drugs are novel. It is much easier to read than either of the two books by Grossman; the arguments are not as thoroughly developed as by Milner; and it is not as detailed as Thompson's book. The overall level of presentation is very similar to the earlier text by Morgan but of course

it is much more up to date. My major reservation is whether we need another textbook of physiological psychology, for the group published between 1967 and 1973 seem adequate as an introduction before the student moves on to more specialised books. But for the student whose reading has to be confined to one book Boddy has provided a sound account with a welcome cognitive flavour.

Who will benefit most from the books? Hassett writes for the undergraduate and his book is unashamedly introductory. Braitenberg will appeal to the widest audience, from student to colleague, because he is such fun and is trying to say something simple and fundamental about the brain; but the reader has to take a lot for granted. The books by Jacobson and Lund are most suitable for advanced students who already know a good deal about the nervous system, and they can hardly fail to become standard reference works for any developmental neurobiologist. Boddy's is the only book that is a student text covering a broad range of topics. It is good, but not clearly better than a number of rivals.

A. Cowey is Reader in Physiological Psychology at the University of Oxford, UK.

Psychology texts

ONE of the joys of working in psychology is the discipline's apparently unlimited ability to borrow from other areas. At times the joy can turn to anguish when the transplant seems to submerge the host but a new development for "grafting" always seem to come along.

Complications for teaching come from the diverse ways in which departments of psychology seem to split up the subject matter—for example, should there be separate courses on thinking and on psycholinguistics; should both be subsumed within a conglomerate memory, language and thinking; should there be a separate course on artificial intelligence (AI); or should all the preceding courses be collected within one course on cognitive psychology? Possibly a solution lies in the emerging discipline of 'cognitive science'—forming a linkage between linguistics, AI and cognitive psychology. It is against this background of shifting boundaries that course texts for psychology have to be assessed.

Artificial Intelligence (Edinburgh University Press: Edinburgh; £5), edited by

Bundy *et al.*, has more claim to be a course-text than many so-called textbooks. The book derives from lecture notes for the 'Artificial Intelligence 2' course given at the University of Edinburgh (one of the few UK centres where full AI courses are available to psychologists). The '2' is perhaps cautionary—not a course for first-year students; and also it represents a very full year's work.

For those planning their own courses programming exercises through the text, and appendices with examination papers and student response to the course should prove invaluable. Collection of the references throughout the text into a bibliography would have been useful. Readers likely to be disappointed with the book would be those working from a cybernetics: brain-theory: engineering background—the six pages on Perceptrons do not sufficiently reflect work within their area.

Comparison texts would include those by Winston, Boden and the Open University Cognitive Psychology course team. Winston's *Artificial Intelligence* (Addison-Wesley, 1977) is a more technical work with few compromises to non-LISPers. It is really for advanced undergraduates and postgraduates, and is perhaps an AI/computer science text rather than a psychology text. The OU

text relies heavily on access to a terminal tied to the SOLO system (specially developed for this course) and seems a difficult text to grasp in isolation. For many humanities students (including linguists, philosophers, and some psychologists) Margaret Boden's *Artificial Intelligence and Natural Man* (Harvester, 1977) provides a good introduction to the area of AI without becoming too embroiled in techniques. But if your psychology department is lucky enough to have access to a suitable computing system then the Edinburgh text is a good introduction to trying out techniques in AI.

Psycholinguistics (Prentice-Hall: Englewood Cliffs, New Jersey; £10.90) by Foss and Hakes lives up to its subtitle—*An Introduction to the Psychology of Language*. Concentration of psychology rather than linguistic theories or developmental processes produces an excellent overview of the chequered area of psycholinguistics. From a murky mixture of mechanical translation, S-R psychology and information theory, through the revolution of Chomskyan grammar, psycholinguistics has reached its present stage of uncertainty and division. Claims to form a separate discipline seem to be fading; merging into more traditional areas of psychology and supplying part of the backbone of cognitive psychology seems more likely.

The introductory chapters provide a good discussion concerning the nature of language, and anchor the book against a linguistic as well as psychological background. Three chapters then cover 'input operations'. An excellent exposition and discussion of speech perception is followed by a comprehensive treatment of comprehension—indicating other sources of information than pure syntax. The section concludes with an integration of sentence understanding with various models of memory. The next section deals with 'output operations' and is divided

into the planning of sentence production and the production mechanisms involved. There is good treatment of the information that speech errors can give to the psychologist interested in underlying mechanisms, and a thorough presentation of rhythmic processes in speech. This leads neatly into three chapters outlining the development of language. There is emphasis on communication skills, understanding and semantics.

The last three chapters of the book are perhaps the most interesting. Building on earlier discussion, they cover reading, language and the brain, and language and thought. The chapter on reading provides a nice summary of experimental work integrated with an interesting model. Language and brain links together a number of rather disparate areas including aphasia, localisation and lateralisation, and species-specificity in a comprehensive manner. The final chapter seems a little unhappy—considering linguistic diversity with an emphasis on Black English and linguistic determinism: language and thought.

Each chapter is well summarised and contains suggestions for additional reading. Good indices and a bibliography complete the book. With the exception of coverage of 'sociolinguistics' (which seems to be social psychologists using language variables as indices of social processes rather than psycholinguistics proper), the book is an excellent text for specialised psycholinguistics courses. Underplaying of relevant AI work and omission of much European work—notably the work on thinking and language by investigators such as Wason and Johnson-Laird—suggest that the integration that the umbrella of 'cognitive science' offers should not be ignored.

A. Conway

A. Conway is a Lecturer in the Department of Psychology at the University of Bristol, UK.

Animal behaviour

HERE are reviewed two new textbooks in animal behaviour aimed at the American undergraduate market. Both assume little or no previous knowledge of anything, and both are written in a chatty, mildly condescending manner, eschewing complexity and encouraging a belief in simple solutions. Both also, as befits the type, are full of absurd and redundant illustrations, although the prize here is unquestionably taken by Seay and Gottfried—with a picture of a supermarket; of numerous smiling infants, some busily taking in nourishment; of adolescents standing on street corners or, if of different sexes, sitting

in one another's laps; of a teacher looking at a blackboard, visitors to a science museum looking at an exhibit, and Jean Piaget looking at children playing. The differences between the two books, however, are greater than the similarities.

D. A. Dewsbury's *Comparative Animal Behavior* (McGraw-Hill: New York and London; £14.95) is the more conventional of the two, essaying a relatively straightforward account of psychological, ethological and (to show we move with the times) sociobiological approaches to the study of animal behaviour. The book has many virtues. It covers a great deal of ground (some of it quite out of the way), seems to be reasonably accurate, and does not always settle for received opinion. Although extremely diffident about it, for example, Dewsbury is willing to

Soon to be available as a Student Paperback.

Plant Virology: The Principles

Adrian Gibbs and Bryan Harrison

This modern exposition of plant virology aims to describe the framework of knowledge about plant viruses and to outline the methods used in obtaining this knowledge. The numerous illustrations include superb electron micrographs—many of them original—and other photographs as well as numerous line diagrams. Thus the framework of the subject is provided and much practical information on how plant viruses can be studied is given.

'The production is excellent, with clear type and illustrations. . . .

Unquestionably this book is a valuable addition to the few on plant viruses and will be welcomed especially by the small band who teach the subject at English-speaking universities.' —*Nature* (of the cloth edition)

Recent 'Studies in Biology'

104 Biological Clocks

John Brady

An introduction to these physiological processes that measure time by some means and do so in relation to environmental time-cues, such as high tide or sunset. This is the first work of its kind intended for the biologically informed but non-specialist reader.

Paper £1.60

105 Liver

W. H. Horner Andrews

The book brings together widely scattered knowledge on the structure and function of the liver and also shows how these functions—of man and other organisms—are interrelated.

Paper £1.70

106 Aquaculture

P. J. Reay

This book brings together some of the more recent advances in aquaculture in order to explore the biological basis of this increasingly important industry and the role of the biologist in its future development.

Paper £1.75

Publication March 23rd.

challenge the conventional assessment of the nature-nurture issue as a pseudo-question. But, for my taste at least, these virtues were outweighed by one pervasive vice: Dewsbury talks down to his readers. The book is permeated with an attitude of 'not in front of the students'. Whenever a topic shows signs of becoming interesting, Dewsbury backs off as if such complex matters were far beyond our capacity to understand. Thus conclusions are proclaimed, but we are never told why they are reasonable. Most biologists, no doubt, reject the theories of Lamarck and of Wynne-Edwards, but it should surely be possible to explain why they do so. Theories must be taken on trust, as they are rarely explicated, certainly not if they contain a hint of mathematics. The concept of an Evolutionary Stable Strategy, however, as Richard Dawkins has shown, can be explained, with numerical examples, in a manner intelligible to a wide range of readers. Dewsbury makes no attempt to do so, and the student must therefore take his word for it that 'the approach appears to have great potential'. Sometimes Dewsbury's reluctance to enter into complicated detail will surely cause much worse confusion than that which he was trying to avoid. Unless already familiar with the problems of navigation, for example, the reader will be quite unable to understand from his account the distinction between Kramer's map and compass theory and Matthew's sun-arc hypothesis of bird navigation; and the sense in which the former is addressed to a simpler question than the latter. Once again, however, it is a reasonably simple matter to illustrate the distinction by reference to the experimental evidence which suggests that Matthews is probably wrong.

Authors are apt to feel hard done by when reviewers complain about the omissions in their books. Dewsbury would perhaps insist that he had no room to go into the necessary detail, but this is largely because he has used his space unwisely. He seems to be obsessed by the need to cover the field, without stopping to ask what should be included in the comparative study of animal behaviour. It is surely reasonable to restrict it to genuinely comparative work, or that which emphasises adaptive function and other evolutionary concepts. It does not need to include the standard facts of sensory and perceptual psychology, conditioning and learning, and physiological psychology. These, as Dewsbury reminds us, are taught in other courses. But this does not deter him from devoting half-a-dozen of his 17 chapters to a necessarily rather cursory survey of these topics. He recounts

some intrinsically interesting facts, but there is little attempt to set them in any theoretical context. His book may be quite useful, but only if students are required to read other matter which will make them think harder.

B. Seay and N. Gottfried, in *The Development of Behavior: A Synthesis of Developmental and Comparative Psychology* (Houghton Mifflin: Boston and London; \$15.50), do not at least waste space or time in the provision of potted information on such standard topics. On reaching the end of their book, however, I found myself at a loss to recall what they had told me. Isolated examples came to mind: an analysis of shopping in a supermarket (hence the picture) in terms of 'super-schemas'; an assurance that love is not a mere epiphenomenon of sex, but a basic need in its own right; and, in case I did not know it, the information that 'lovers also engage in precopulatory behaviour, with participation in sexual intercourse dependent upon local custom and the stage of development of their relationship'. These stood out from an otherwise rather humdrum assortment of standard topics, some superficially recounted facts, and many more uncritically accepted theories. Bowlby's views on attachment, Whorf's on linguistic relativity, and Seligman's on preparedness in learning are all presented to us without any serious suggestion that they might not stand

up to critical examination. The book starts with a series of chapters on 'Phylogenetic Set', 'Ontogenetic Set' and several more sets, defined as 'pre-disposing influences on behavior'; while Part II, just to be different, is organised around various behavioural systems, such as affection and social organisation, which, the reader is asked to remember, are all affected by an interaction of all these sets.

As its subtitle suggests, the book is a curious mixture of comparative psychology and ethology on the one hand and human developmental and social psychology on the other, with a dash of social anthropology thrown in for good measure. But it is not, alas, a synthesis. Throughout the book, we are switched back and forth from studies of animals to the study of man, with little discussion of the relevance of one to the other. It is not so much that the authors are rash or glib in their willingness to generalise, as that they do not involve the student in any serious consideration of the issues involved. Unlike Dewsbury, they have not chosen so to fill their book with facts that there is no room left for discussion: the space is there, but it is largely filled with platitudes.

N. J. Mackintosh

N. J. Mackintosh is Professor of Experimental Psychology at the University of Sussex, Brighton, UK.

Sensory physiology

Two recent books on sensory physiology have a similar aim and are therefore reviewed here together. The publishers have to be congratulated for producing two compact, well printed and well illustrated books.

Jacqueline Ludel's *Introduction to Sensory Processes* (Freeman: San Francisco and London; hardback \$17, paperback \$9) has the advantage that it is written by one author and this gives uniformity of style. She goes to great efforts to define accurately every new term, often illustrating the point with a clearly drawn figure. The book has a considerable number of colour illustrations which do help understanding. She has mastered the art of a good teacher—tell the student everything three times without boring him. This is a book to be read slowly and thoughtfully. It is reasonably up to date and certainly adequate for an introduction to the subject of sensory physiology.

Fundamentals of Sensory Physiology (Springer: New York and Berlin; paper-

back OM 33.60, \$16.80) is very well edited by Robert Schmidt so that, although there are seven different contributors, the style is uniform. As each section is written by an expert in the field it is accurate and fairly up to date. Again, each new scientific word or definition is carefully defined and printed in bold type. At the end of each chapter there are a number of thought provoking questions which ensures that the reader has thoroughly understood the contents.

Both books give excellent references, readily obtainable, for further advanced reading. Teachers of the subject will wish to have both books to hand as there are different teaching points and illustrations in each of them. Individual readers will have a hard task deciding which one to purchase as both are so good. Libraries will wish to have a copy of both. Both will appeal to physiologists, psychologists and scientists in industry dealing with man-machine interactions—for example, photography and sound recording.

newly on the market

Student and teaching microscope. Zeiss. The Zeiss KF 2 low-cost student and teaching microscope is compact, has very few controls and all electrical components are built into the stable base. Turning a knob on the base to switch on the illuminator, placing a slide on the stage, and focusing are all that is needed to obtain a brilliant, evenly illuminated image. All optical components are parfocal and permanently centred. The KF 2 is ruggedly built to withstand heavy duty. Its movable parts do not show wear and tear and the finish is corrosion-resistant.

Circle No. 31 on Reader Enquiry Card.

The Zeiss KF2

PTFE filters. Sartorius. The new range of PTFE filters, manufactured by Sartorius, show great chemical resistance and high temperature stability and have excellent hydrophobic properties. These filters are therefore especially suited for particle and sterile filtration of gases, with very good flow rate. They are available in pore sizes 0.2, 0.45, 1.0 and 5.0 μm , with diameters ranging from 13 to 293 mm.

Circle No. 32 on Reader Enquiry Card.

Mass spectrometer. Varian. The double focusing MAT 312 mass spectrometer system from Varian has a guaranteed resolution of $>35,000$ (10% valley). A peak matching device for precise mass determination is included in the standard configuration. A large variety of accessories are available and technical features include the maintenance-free high vacuum pumping system with turbo-molecular pumps and a direct evaporation system.

Circle No. 33 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.

Scanning fluorescence spectrometer. Perkin-Elmer have introduced a scanning fluorescence spectrometer. The Model 3000 uses microprocessor controlled, stepper motor driven monochromators, with digital display of wavelength and 6 wavelength memories. Excitation spectra may be scanned over the range 230–720 nm and emission spectra over the range 250–800 nm. The instrument uses a stroboscopic xenon source. Among its features is the ability to automatically produce fully corrected excitation spectra, achieved by using a rhodamine quantum counter and ratio recording electronics. Operation of the instrument is by push button control.

Circle No. 34 on Reader Enquiry Card.

Oximeter. British American Optical have recently introduced the AO Unistat oximeter into their range of medical equipment. This machine gives a value of oxygen saturation in blood in under 20 s. To obtain this information, the samples of blood (only 0.4 ml of whole blood is required) are placed in one of the disposable cuvettes and the per cent of oxygen saturation is read off on the large LED display.

Circle No. 35 on Reader Enquiry Card.

Gas-tight syringes with removable needles. Hamilton. Available from V. A. Howe are the new range of Hamilton 1000 and 0700 series gas-tight syringes with removable needles. There are six models, from 10 μl to 500 μl , with advantages including that the plunger, glass barrel and needles are field replaceable, that the needle plugs straight into the Teflon ferrule and is securely held in place by a locking nut, and the replaceable Teflon plunger tips allow injections at up to 7 atms.

Circle No. 36 on Reader Enquiry Card.

Microcellcounter. TOA Medical Electronics. A microcellcounter capable of performing RBC, WBC and platelet counting without changing transducers has been introduced by TOA Medical Electronics. The Sysmex PL-110 is a fully automatic system following sample introduction, including data printout with the Sysmex DP-411 printer option. Other options include the Sysmex auto dilutor Ad-220, which reduces pipetting errors to well under clinically acceptable levels. The counter allows fingertip control and visual inspection of the aspiration and ejection phases.

Circle No. 37 on Reader Enquiry Card.

Temperature linearisation amplifiers. Philips. Two temperature linearisation amplifiers have been introduced by Philips. The units, nominated PM9873/01 for Fe-Const, type J, and PM9874/01 for NiChr-NiAl, type K, provide an output of 1 mV per $^{\circ}\text{C}$ over the full temperature range of the thermocouple and include automatic cold junction-compensation, within a linearity of $\pm 1^{\circ}\text{C}$. Both units are basically designed for use with Philips modular compact recorders PM 8202 one line and PM 8222 two line.

Circle No. 38 on Reader Enquiry Card.

Digital pH meter. Orion. The 501 digital pH temperature system from Orion displays pH readings from 0.00 to 14.00 with precision to ± 0.01 pH (the system also reads out in mV). Temperature measurements can be made over -5° – 100°C with $\pm 0.1^{\circ}\text{C}$ accuracy. Also supplied with the 501 are: an unbreakable, platinum resistance probe which provides accurate automatic temperature compensation and digitalised temperature readings; and an unbreakable 91-05 gel-filled GX electrode that never requires refilling with KCl.

Circle No. 39 on Reader Enquiry Card.

The Orion 501 digital pH system

Radiometer/photometer. Glen Creston now offer the model 730A radiometer/photometer for measurement of both continuous and pulsed light sources. Readout is direct in any one of 14 optical and electrical units. Both BCD and 0–1 V analogue outputs are standard. The wavelength range covered is 200–1,100 nm. The sensor consists of a stable, UV enhanced silicon photodetector with an area 1 cm^2 . Radiometric and photometric filters are provided.

Circle No. 40 on Reader Enquiry Card.

Float zone crystal growth systems. Metals Research. These modular systems, which can incorporate Czochralski, Bridgeman, RF float zone and Kyropoulos crystal growth facilities, allow continuous visual assessment of crystal growth. They have a choice of two chamber sizes and a wide range of accessories. The system avoids the need for temperature control equipment because the twin-walled, water-cooled reactor chambers are transparent, the outer walls being made of Pyrex and the inner of fused quartz. Using the standard RF induction heating system, vacuum, inert gas, oxidising or reducing atmospheres may be used at temperatures up to 1,800 °C. The system is modular so that the basic equipment can be added to at any stage. The basic unit consists of the main frame plinth, the selected heating system, furnace support column and Bridgeman lowering mechanism for the crucible or mould.

Circle No. 41 on Reader Enquiry Card.

Metals Research float zone system

Direct-drive vacuum pumps. GCA/Precision Scientific Group has introduced seven new models to its line of direct-drive vacuum pumps. This brings the Precision line of two-stage direct-drive pumps to 10, ranging in pumping capacity from 20 to 475 l m⁻¹. The new pumps range in size from 90 to 475 l m⁻¹. They are capable of an ultimate vacuum of 0.1 μm, and can pump at 50% maximum throughput at 1 μm. Extremely low operating noise levels are a key feature of the new units. Exceptionally low vibration and an internal exhaust baffle contribute to the pumps' quiet operation.

Circle No. 42 on Reader Enquiry Card.

Reagent grade water for elemental analysis. Millipore. To meet the growing demand for purer water, Millipore has developed the Milli-Q system, which produces reagent grade water of 18 MΩ resistivity free of organic, inorganic and particulate contaminants. Some typical applications are preparation of standards and sample make-up in AA and other elemental analysis, and organic determinations with GLC and HPLC.

Circle No. 43 on Reader Enquiry Card.

Aerosol and particulate monitoring systems. Phoenix Precision Instruments. A range of aerosol systems for detecting and monitoring airborne contaminants, indoors or out, is available from Phoenix Precision Instruments. The systems comprise models JM-5000, featuring logarithmic output, JM-6000, with 5-range selectable linear amplification, and JM-7000, a combination log linear instrument. Designed for testing and monitoring HEPA filters, these compact and completely self-contained photometers give direct readings in mass concentrations to eliminate statistical calculations.

Circle No. 44 on Reader Enquiry Card.

Edax system for Philips microscopes. Pye Unicam. An energy dispersive X-ray analysis system can now be ordered from Pye Unicam for use in conjunction with Philips scanning and transmission microscopes or columns. Features of the Edax 9100 series analytical system include: a 4000-channel data memory with 10⁶ capacity per channel; automatic vertical size normalisation of compared spectra; unique function keys that eliminate the typing of mnemonic codes; expansion for WD, EELS and other multi-task function.

Circle No. 45 on Reader Enquiry Card.

Computer system. Control Data. The Control Data Cyber 203 is a large-scale, high-speed logical and arithmetic computer system. It uses integrated circuits and offers advanced design features such as vector stream processing (up to 10⁸ results per s), virtual addressing, hardware macro instructions and a 2 × 10⁶ word semiconductor memory. It also offers separate scalar and array processing units, and functional units specifically designed for sequential and parallel operations on single bits, 8-bit bytes, and 32- or 64-bit floating-point operands and vectors. Virtual addressing uses a high-speed mapping technique for converting a logical address to an absolute storage address.

Circle No. 46 on Reader Enquiry Card.

FMOC amino acids. Chemical Dynamics Corporation announce the availability of a new protecting group for amino acids, the 9-fluorenylmethyloxy carbonyl (FMOC) group. This protecting group is a base-labile and acid-stable protecting group, easily removed by amine bases such as ammonia or piperidine. The FMOC group is ideally suited to the synthesis of peptides with special side-chain protecting problems, as it is completely compatible with side-chain BOC groups and *t*-butyl esters and ethers.

Circle No. 47 on Reader Enquiry Card.

Epitaxial system. Metals Research. New from Metals Research is an RF heated, epitaxial and chemical vapour deposition system—the system 100—designed as a low cost equipment for research and pilot plant production applications. The system 100 is based on two separate consoles, one for the gas control system and one for the quartz reaction cell. The consoles are made from polyurethane resin enamelled sheet steel and are 1,750 mm high × 1,070 mm wide. Consoles are bolted together to form a single unit. System features include interlocking for operator safety, air or water cooled cells and horizontal laminar flow.

Circle No. 48 on Reader Enquiry Card.

Lipid panel assays. Bio-Rad Laboratories are now offering a comprehensive range of assays in the field of lipid chemistry, the Bio-Rad HDL cholesterol assay, Quantazyme cholesterol, Quantazyme triglycerides and the Bio-Gram A lipoprotein electrophoresis test system. The HDL cholesterol system comprises a one vial, predispensed, lyophilised separation system and eliminates refrigeration steps. Both the cholesterol and triglycerides assay systems are single vial, fully enzymatic, easily automated and end-point assays.

Circle No. 49 on Reader Enquiry Card.

Cell disintegrator. Biox. The Biox X-Press cell disintegration system operates at -20 °C, taking advantage of the shearing stresses generated when ice is forced through a narrow orifice at 28,000 p.s.i. The method is rapid, easy to use and the low temperature, maintained throughout the process, prevents destruction of heat-labile components. The disintegration unit itself is autoclavable and corrosion resistant.

Circle No. 50 on Reader Enquiry Card.

Control sera. Bio-Rad Laboratories announce the availability of an extended range of "Lyphochek" control sera. Lyphochek comprises a range of assayed and unassayed lyophilised human control sera for both automated and manual procedures, in addition to a serum reference standard. All these materials are reported to be of outstanding consistency, reliability and stability.

Circle No. 51 on Reader Enquiry Card.

Acoustic emission system. EMI Electronics. The acoustic emission system from EMI is capable of predicting, detecting and locating fatigue cracks in large steel structures. The system uses a Data General mini-computer with a software package designed to provide a range of characterisation processes capable of distinguishing between background noise and genuine crack extension noise. All processing and recording equipment is mounted in a standard 6 ft×19 inch rack. An associated graphics display shows not only the relative positions of emissions but also analyses their characteristics and provides a display of emission density. The system is available for hire or for sale.

Circle No. 52 on Reader Enquiry Card.

The EMI acoustic emission system

Hoffman modulation contrast system now available for Nikon SC microscope. The Nikon SC microscope is now available in a model equipped with the Hoffman modulation contrast system. The system is especially useful in tissue culture studies. The images produced appear three-dimensional, and the system is not affected by the birefringence exhibited by many biological specimens. It uses a modified standard 40× objective, with special built-in modulator element, and a matching slit aperture which fits into a pre-aligned mounting on the condenser.

Circle No. 53 on Reader Enquiry Card.

Anti-human β_2 -microglobulin antibody. Sera-Lab announce the introduction of a monoclonal antibody to β_2 -microglobulin. The material complements two other monoclonal antibodies, directed against a marker on chromosome six, and these three antibodies will form a useful screening panel for the close mapping of HLA markers. The material is suitable for techniques using precipitation and also for labelling with radioisotopes.

Circle No. 54 on Reader Enquiry Card.

Digital image analysis system. Zeiss. A unique and simple quantitative image analysis system, called MOP, has been introduced Carl Zeiss. The special feature of this system is the interaction of the operator's discriminating judgment with the high-speed calculation ability and memory of its microcomputer. The images to be analysed can be in the form of photographs including X-rays, projections and drawings, or they can be directly evaluated through a microscope. The system consists of a compact hybrid microcomputer and a multi-purpose measuring tablet. It has the ability to accurately measure up to 8 parameters simultaneously and the capacity to summarise and store data in up to 20 separate channels. In addition, as a stand-alone system, it can determine percentages, averages, standard deviations, and area differentials. It is also capable of elaborate distribution analysis. The MOP is portable, requires no installation and practically no operator training.

Circle No. 55 on Reader Enquiry Card.

Ultra-fast film for tritium detection. LKB introduces a high-speed film for gross autoradiography of low-energy emitting radio-isotopes such as tritium and ^{125}I . The film, named LKB Ultra-film ^3H , is specially designed for direct high-speed autographic applications in autoradiography of tissue sections, electrophoresis and electrofocusing in thin layer polyacrylamide and agarose gels, and paper electrophoresis and thin layer chromatography. It is 12–64 times faster than conventional X-ray films for tritium detection. With its transparent, uncoloured backing it is also convenient for photocopying, making enlargements and direct display in overhead projectors.

Circle No. 56 on Reader Enquiry Card.

Rhodamine-conjugated immunoglobulin fractions of antisera. Accurate Chemical and Scientific Corporation announces the availability of five new tetramethylrhodamine-conjugated immunoglobulin fractions of antisera. Tetramethylrhodamine isothiocyanate isomer R has been used for the labelling. R 151, rabbit anti-human IgG specific for γ -chains; R 152, rabbit anti-human IgM, specific for μ -chains; R 154, rabbit anti-human κ light chains; R 155, rabbit anti-human λ light chains; R 156, swine anti-rabbit immunoglobulin. Free rhodamine has been removed from these products by gel filtration, and optimum labelled antibody molecules have been isolated by ion exchange chromatography.

Circle No. 57 on Reader Enquiry Card.

Metal film detectors for lasers. Rofin has introduced a new type of detector which consists of a metal film on an aluminium substrate and which has a very high power handling capability. This, in addition to its broad spectral response (visible to $>30\ \mu\text{m}$) makes it ideal as a general purpose laser detector system. A unique feature of the new device is that it can be used for position sensing. Position sensitivities in the μm range are routinely achieved. The detector has a flat response from D.C. to $>10\ \text{kHz}$, and will respond, with lower sensitivity, to MHz frequencies with rise times of less than $1\ \mu\text{s}$. Active areas up to $10''$ diameter are available.

Circle No. 58 on Reader Enquiry Card.

Trace metal-free pipette tips. Brinkmann. Brinkmann Instruments have introduced trace metal-free pipette tips for use with Eppendorf pipettes, sizes 1 to $100\ \mu\text{l}$. The pipette tips are manufactured from non-wetting virgin polypropylene and contain no trace metals or other contaminants. These colourless tips are supplied in 20 sealed bags of 50 tips each inside a shipping/storage carton containing 1,000 tips.

Circle No. 59 on Reader Enquiry Card.

Freeze-drier. Techmation. A heavy-duty freeze-drier for research or pilot production has been introduced by Techmation. The VirTis Freezemobile II, with a total condensate capacity of 18 l, can achieve temperatures of $-55\ ^\circ\text{C}$ in less than 20 min as standard and $-85\ ^\circ\text{C}$ with optional cascade freezing. The condenser has a clear acrylic cover through which the user can observe the ice build-up during drying. An automatic hot gas quick defrost is available which allows the complete removal of the 18-l ice plug in 3 h. Five base models are available including one with a built-in shell freezing bath and twin condenser units.

Circle No. 60 on Reader Enquiry Card.

APPOINTMENTS VACANT

UNIVERSITY OF STRATHCLYDE

Applications are invited from graduates in Operational Research for a

LECTURESHIP

In the
DEPARTMENT OF
OPERATIONAL RESEARCH

Candidates should have teaching and research experience in Operational Research and/or substantial experience of Operational Research in the field.

Salary scale £3,883 to £7,754 (under review) with placing according to qualifications and experience. Superannuation benefit.

Application forms and further particulars (quoting 10/79) and enclosing a self-addressed envelope (9in by 4in), may be obtained from the Academic Appointments Officer, University of Strathclyde, Royal College Building, 204 George Street, Glasgow G1 1XW with whom applications should be lodged by March 31, 1979.

9822(A)

UNIVERSITY OF ZÜRICH INSTITUTE OF INORGANIC CHEMISTRY POSTDOCTORAL RESEARCH CRYSTALLOGRAPHER

Applications are invited for a post-doctoral position in X-ray-crystallographic work mainly on coordination compounds. Good training in crystallography and experience in single crystal structure determination is a necessity. Well equipped laboratory (including low temperature and high temperature X-ray-crystallography).

The initial appointment would be for one year, with extension possible for two or more years. Salary range Swiss francs 40,000 to 45,000 per year (current exchange: £12,000 to £13,400 per annum sterling).

Applications with curriculum vitae and names of two referees should be sent as soon as possible to Dr Erich Dübler, Institute of Inorganic Chemistry, University of Zürich, Winterthurerstrasse 190, 8057 Zürich, Switzerland.

9904(A)

The British Council invites applications for the following post:

UNIVERSITY OF SRI LANKA Colombo Campus SENIOR LECTURER IN FISHERIES BIOLOGY (Sri Lanka)

Qualifications. Candidates, men only, should hold Ph.D. and have at least 4 years postdoctoral experience in marine fisheries research and/or development. Knowledge of marine or freshwater aquaculture an advantage. Duties include teaching at postgraduate level and supervision of research.

Benefits: Personal allowance free furnished accommodation and other benefits. 2 year contract.

Salary: £5,681 to £7,707

Return fares are paid. Local contracts are guaranteed by the British Council. Please write briefly stating qualifications and length of appropriate experience, quoting reference number and title of post, for further details and application form to The British Council (Appointments), 65 Davies Street, London, W1Y 2AA.

9879(A)

UNIVERSITY OF CAMBRIDGE ANIMAL PRODUCTIVITY/ NUTRITION

Applications invited for a University Demonstratorship in Animal Productivity/Nutrition in the Department of Applied Biology. Qualifications—good Honours degree, research experience in some aspect of animal productivity related to nutrition and competence in biometry. Salary in scale £4,133 to £5,129. Pensionable under U.S.S. Limited contribution to removal expenses. Further details from and applications including full personal particulars, list of publications and names and addresses of not more than three referees to the Secretary, Faculty of Biology 'A' Appointments Committee, Department of Applied Biology, Pembroke Street, Cambridge CB2 3DX later than March 31, 1979.

9891(A)

SEALE-HAYNE COLLEGE NEWTON ABBOT, DEVON LECTURER IN ANIMAL PRODUCTION

Applications are invited from suitably qualified graduates with teaching, research or appropriate industrial experience. Duties include teaching degree and diploma students.

Salary based on Scales of Salaries for Teachers in Establishments for Further Education, England and Wales, Lecturer Grade II (£4,101 to £6,558 per annum).

Applications to and further particulars from, The Principal, Seale-Hayne College, Newton Abbot, Devon, TQ12 6NQ.

9849(A)

THE UNIVERSITY OF BIRMINGHAM Faculty of Medicine and Dentistry DEPARTMENTS OF IMMUNOLOGY AND PHYS. RESEARCH ASSOCIATE

A good honours life sciences degree is required to assist in the department of *in vitro* and *in vivo* cytotoxic assays of antitumour antibody bound to cyclotron-produced emitting isotopes. Postgraduate experience with small animal models, immunology or radio handling techniques would be a plus.

The project, financed by the MRC, is for three years. Salary will be the Research Associate Range 1B scale—£3,384 to £4,882 superannuation. The maximum salary will be £3,634.

Further information may be obtained from the Assistant Registrar, Medical School, Birmingham B15 2TT with whom applications (three including a curriculum vitae) should be lodged not later than March 1979. Please quote reference IMM/179.

9888

TECHNICIAN (Grade 5) required in Department of Microbiology, University of Reading. Main duties are supervision of laboratory service section dealing with teaching and research in Microbial Physiology Biochemistry, equipment for tea and research, chemical stores according to qualifications and experience in range £3,186 to £3,726 (under review). Further details available on request. Apply, stating qualifications and experience and the names of two referees, to Ref T.N. 74A, to Assistant 1 (Personnel), University of Reading, Whiteknights, Reading, RG6 2AA.

9831

UNIVERSITY OF EDINBURGH DEPARTMENT OF MICROBIOLOGY

Applications are invited for post of

UNIVERSITY DEMONSTRATOR

in the Department of Microbiology. Candidates should normally be in their third year of graduate research in any field of Microbiology.

Salary scale £3,384 to £4,882 per annum.

Further details are available from the Secretary to the University, Old College, South Bridge, Edinburgh EH8 9YL, to whom applications (five copies), giving the names of three referees, should be sent not later than March 1979. Please quote Reference I.

9872C

MICROBIOLOGIST/ IMMUNOLOGIST

Bayer AG, West Germany, who have been active in pharmaceutical research for about 100 years, wish to appoint a person to establish a new unit within the Chemotherapy Department at their headquarters in Elberfeld, West Germany.

Applicants should have experimental experience both in microbiology and immunology and should preferably be medically qualified holding a higher degree. They should have sufficient experience to build up a new unit to follow a new line of therapeutic research. Applicants should be aged 30-40.

A knowledge of German would be an advantage but is not essential.

An attractive salary will be offered, together with additional benefits associated with a major Company.

Applications should initially be sent in confidence to:

Dr. H. B. Allen, Medical Director
Bayer UK Limited, Pharmaceutical Division
Haywards Heath West Sussex RH16 1TP

Bayer thinks of tomorrow—today

9903(A)

**JAMES COOK UNIVERSITY
OF NORTH QUEENSLAND
LECTURER**

IN THE DEPARTMENT OF
TROPICAL VETERINARY SCIENCE
(VETERINARY MICROBIOLOGY)

A vacancy exists for a Lecturer in Veterinary Microbiology in the Department of Tropical Veterinary Science. Applicants should have wide Post-graduate experience in Veterinary Microbiology relating to diseases of livestock. Expertise in Bacteriology is preferred and a background of research in Contemporary Immunological methods is essential. The appointee will be responsible for the presentation of graduate courses and the development of research on disease problems in food animals and will also be required to supervise research by graduate students undertaking M.Sc. and Ph.D. programmes.

The salary range for the position of Lecturer is \$A15,786 to \$A20,737 per annum and commencing salary will be determined according to qualifications and experience. Conditions of appointment include F.S.S.U. type superannuation, study leave, invalid pension scheme, housing assistance and allowance for travelling and removal expenses on appointment. Additional information and application forms are obtainable from the Registrar, Post Office, James Cook University, Qld 4811, Australia, or from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF. Applications close March 31, 1979. 9821(A)

**NG'S COLLEGE HOSPITAL
MEDICAL SCHOOL
(University of London)**

Denmark Hill,

London SE5 8RX

**DEPARTMENT OF
CHEMICAL PATHOLOGY
RESEARCH FELLOW**

Applications are invited for the above post, which will be supported by a grant from the Cancer Research Campaign.

The successful applicant, who should have a Ph.D. degree or equivalent experience, would join a small group studying the mechanism of steroid hormone action, under the direction of Dr M. Norman.

The project will involve the use of human lymphoid cell line for the *in vitro* investigation of interactions between steroids and other drugs used in the treatment of leukaemia. Experience in the fields of tissue culture or mechanism of drug action would be desirable but not essential.

The appointment will be for three years, with a starting salary of £4,882 annum plus £450 London Weight Allowance. Further particulars may be obtained from the Secretary to the Medical School to whom applications, including full curriculum vitae and naming two referees, should be sent by March 23, 1979. 9868(A)

**UNIVERSITY OF ESSEX
LECTURESHIPS IN THE
DEPARTMENT OF BIOLOGY**

Applications are invited for two lectureships in biology tenable from October 1, 1979 (salary scale £3,883-£7,754 under review). One appointment will be for an animal biologist, preferably with interests in physiology and immunology, the other for someone interested in the molecular basis of development or cell biology.

Applications (nine copies), including curriculum vitae and the names and addresses of two referees, should reach the Registrar (AG/66/N), University of Essex, Wivenhoe Park, Colchester CO4 3SQ, from whom further particulars of the research and teaching are available, by March 16, 1979. 9864(A)

Drug Metabolism Section Heads Biosciences Research Centre Great Burgh, Epsom

As a result of the Company's expanding research activities, a new Drug Metabolism Unit is being established at Great Burgh. The Unit, which should be ready for occupation in July 1979, will contain three sections: Analytical Biochemistry, Chemistry and Metabolic Biochemistry. As part of the Clinical Pharmacology Department, the Unit's responsibilities will include the investigation of drug metabolism in experimental animals and man, with particular interest in the areas of biosciences and chemotherapeutic agents.

Two Section Heads are required (the Head of the Chemistry Section has already been appointed), who will assist the Head of the Unit in the equipping of the laboratories and the appointment of staff within their respective sections, before the Unit becomes fully functional.

Analytical Biochemistry

The Head of Analytical Biochemistry Section will be responsible for a team concerned with the development and application of methods for the quantitative analysis of drug substances and their metabolites in biological systems and for the design and initiation of pharmacokinetic studies. Candidates for this position should have broad experience in the use of H.P.L.C., G.L.C., GC-MS, automated analysis and other relevant analytical techniques used in modern biochemical analysis.

Metabolic Biochemistry

The Head of Metabolic Biochemistry Section will be responsible for a team investigating the metabolic fate of pharmacological agents in laboratory animals and man. The successful candidate will have had at least three years post-doctoral experience in the field, be well informed on the theoretical concepts involved and possess a substantial knowledge of relevant practical techniques.

The nature of the work in the Drug Metabolism Unit will necessitate considerable liaison between the three Section Heads, the Head of the Unit, and other scientific staff.

The positions which are open to male and female candidates will command a competitive starting salary and a range of other benefits including non-contributory pension and free life assurance. For an application form please telephone Burgh Heath 53344, Extension 208, or write to: **The Site Personnel Manager, Beecham Pharmaceuticals, Research Division, Biosciences Research Centre, Great Burgh, 1 Yew Tree Bottom Road, Epsom, Surrey.**

Beecham Pharmaceuticals

9910(A)

Pre and postdoctoral positions are available for studies on the protein synthesising system with special emphasis on structure and function of mRNP particles, ribosomes—topography, biogenesis and function—under various conditions of growth and development. Teaching opportunities available. Reply with resumé to: Professor Bruce H. Sells, Laboratories of Molecular Biology, Faculty of Medicine, Memorial University of Newfoundland. 9751(A)

APPLICATIONS are invited to fill three new permanent faculty positions in geophysics, ocean-oriented engineering and physical/meteorological oceanography to expand present twelve-person faculty. Six-credit graduate (M.Sc., Ph.D.) and undergraduate level teaching loads offer a relatively unencumbered opportunity to develop research interests in national and international areas while living in an ideal climate. Ph.D. degree required. Rank and salary open. Contact N. W. O'Hara, Head, Dept. of Oceanography and Ocean Engineering, Florida Institute of Technology, Melbourne, FL 32901. (305) 723-3701. Equal opportunity/affirmative action employer. 9847(A)

**UNIVERSITY OF LONDON
CHAIR OF
HUMAN ENVIRONMENT
tenable at the
Institute of Archaeology**

The Senate invites applications for the above Chair. Further details should be obtained from the Academic Registrar (N), University of London, Malet Street, London WC1E 7HU, before submitting applications (10 copies). Closing date: March 31, 1979. 9900(A)

Director

National Center For Toxicological Research Food and Drug Administration

The U.S. Food and Drug Administration is seeking candidates for the position of Director of the National Center for Toxicological Research (NCTR). The Center, an interagency facility, conducts research programs on the biological effects of potentially toxic chemical substances found in the human environment. The Director of NCTR provides leadership and direction to all Center operations and provides scientific liaison between NCTR and other Government agencies, private organisations and the worldwide academic, scientific and medical communities. The Center is located in Jefferson, Arkansas and has a staff of approximately 600 employees. The Center is well-equipped with sophisticated and modern laboratories to support advanced research in virtually all areas of toxicology.

FDA is looking for candidates of recognised scientific distinction and administrative ability. Candidates should possess an advanced degree in a relevant field of science (such as a Ph.D. in biochemistry, pharmacology, toxicology, or statistics, an M.D., or a D.V.M.). The position also requires appropriate research experience and an association with multi-disciplinary issues. This is a Civil Service position that pays up to \$47,500 per year in basic salary. The Director will also be eligible to receive performance bonuses and special stipends that may result in a higher total pay. This position has been designated for inclusion in the Federal Government's Senior Executive Service (SES), and the selectee will be required to enter the SES. Information on the SES will be available for interested applicants.

Send curriculum vitae and/or Standard Form 171 (Personal Qualifications Statement) and bibliography to:

HEW/Food and Drug Administration,
NCTR Search Committee,
c/o Ms. Patricia Sykes,
Rm. 9-89, 5600 Fishers Lane,
Rockville, Maryland 20857, U.S.A.
FDA/An Equal Opportunity Employer.

9784(A)

Department of Agriculture for Northern Ireland and The Queen's University of Belfast

Applications are invited in respect of the combined post of—

Head of Agricultural and Food Bacteriology Research Division of the Department of Agriculture; and

Professor of Agricultural and Food Bacteriology in the Faculty of Agriculture and Food Science, The Queen's University of Belfast.

which will become vacant in April 1979.

SALARY SCALE

The appointment will be made within the scale of £10,043-£11,300 which is subject to review with effect from 1 April, 1979.

There is a non-contributory pension scheme apart from 1½% deduction from salary to cover widows and dependants benefits in the case of male officers.

APPLICATIONS

Please write or telephone for an application and further details quoting job reference SB 129/79/NA to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (telephone Dundonald 4585 ext 304).

Completed forms must be returned to arrive not later than 12 April, 1979.

9886(A)

**NORTHERN IRELAND
CIVIL SERVICE**

DALHOUSIE UNIVERSITY DEPARTMENT OF BIOLOGY

Faculty position: Forest Resource Ecologist, in Department of Biology with participation in the programme of the Institute for Resource and Environmental Studies.

Rank: Probably Assistant or Associate Professor. The individual appointed should be capable of teaching applied Plant Ecology and Forest and Land Resource Evaluation and Management to undergraduates and graduate students and of supervising graduate students in both the Master of Environmental Studies and the Master of Science programmes.

Research interests in Renewable Energy and Forest Management and Conservation, and in Forest Ecosystem Nutrient cycling. Ability to relate research to the needs of government, industry and the community.

Submit C. V. and 3 letters of reference by March 30, 1979 to Chairman, Department of Biology, Dalhousie University, Halifax, Nova Scotia, Canada B3H 4J1. 9874(A)

ROYAL POSTGRADUATE MEDICAL SCHOOL PEPTIDE SECTION (DEPARTMENT OF CHEMICAL PATHOLOGY) TECHNICIAN/SCIENTIFIC OFFICER

required in the Peptide Laboratory to take part in the synthesis of novel peptide hormone analogues. Applicants should possess H.N.C. or a degree in chemistry or biochemistry and have experience and/or interest in organic synthesis. The post is tenable for 18 months in the first instance, with a possibility of further extension.

Salary within the range £3,646 to £4,199 placing dependent on qualifications and experience.

Application forms may be obtained from the Personnel Office, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 0HS quoting reference number 4/203/N.

9810(A)

UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF BIOCHEMISTRY POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited from biochemists, molecular biologists or microbial geneticists to join a group investigating DNA repair and genetic recombination in *Escherichia coli*. The project is supported by the Medical Research Council until March 31, 1981. The work will involve a combination of biochemical and genetic techniques, and previous experience in nucleic acid biochemistry, molecular genetics, enzyme purification or DNA cloning would be advantageous.

Commencing salary will be within the scale £3,883 to £6,555 (under review) with full superannuation provision.

Applicants should send a curriculum vitae and the names of two referees to Dr P. T. Emmerson, Department of Biochemistry, University of Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU. 9848(A)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF VETERINARY PATHOLOGY TECHNICIAN

in the histopathology teaching and diagnosis laboratory. Candidates should possess HNC or equivalent and have wide experience in histopathological techniques. Salary in a range up to £4,365 p.a. (under review).

Application forms may be obtained from The Registrar, The University, Quote Ref: RV/510/N. 9881(A)

UNIVERSITY OF THE WEST INDIES JAMAICA

Applications are invited for the of LECTURER/ASSISTANT LECTURER IN THE DEPARTMENT OF BOTANY. Preference will be given applicants who possess a first degree with majors in Botany and hold graduate qualifications or have interest and teaching experience in Biology of the Lower Plant Group. The appointee will be required to take up duties as soon as possible. Scale: Lecturer—J\$8,913 to J\$13,136 p.a., Assistant Lecturer: J\$7,236 to J\$9,226 p.a. (£1 Sterling = J\$3. FSSU. Study and Travel Grant, furnished accommodation will be by the University at a rental of 20% of salary or a housing allowance of 20% of salary will be paid. For passages. Detailed applications (copies) with curriculum vitae naming three referees should be as soon as possible to the Registrar, University of the West Indies, M. Kingston 7, Jamaica. Applicants resident in the UK should also send copy to the Inter-University Council, 90-91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 9883(A)

UNIVERSITY OF ADELAIDE

Applications invited from persons familiar with and experienced in NMR techniques and desiring to work on biologically relevant problems appointment for three years as RESEARCH FELLOW (X1905) (logical NMR Spectroscopy) to work on a project entitled "Aqu interactions between hormones phospholipid membrane constituent. The work is funded by an A.R.C. grant and will be supervised by Professor L. G. Paley, Department of Plant Physiology, Waite Agricultural Research Institute, to whom enquiries about the project may be addressed.

SALARY SCALE: \$A15,179 by (1) by 680 (2) to \$A17,220. economy class airfare and a contribution towards removal expenses will be provided. It is expected that there be provision for superannuation.

APPLICATIONS, in duplicate, including personal, education and professional details, and confidential letter of recommendation pertaining to position from three referees, should reach the Registrar of the University G.P.O. Box 498, Adelaide, S Australia, 5001 not later than March 31, 1979. 9869(A)

MONASH UNIVERSITY Melbourne, Australia DEPARTMENT OF PATHOLOGY AND IMMUNOLOGY JUNIOR RESEARCH FELLOW or RESEARCH FELLOW

Junior Research Fellow or Research Fellow with biophysics qualifications or relevant experience to help on a Becton-Dickinson FACS-11 fluorescence cell sorting in immunological and cancer research directed by Professor R. C. Nairn, Mc Medical School, Alfred Hospital. be interested in flow cytometry computer data analysis. Position available immediately. Salary: Junior Research Fellow \$A13,606 to \$A1 per annum; Research Fellow \$A1 to \$A19,940 per annum. Temporary housing. Application procedure available from the Academic Registrar, Monash University, Wellington 1 Clayton, Victoria, 3168, Australia. the Association of Commonwealth Universities (Apspts), 36 G Square, London WC1H 0PF. Enquiries to Professor R. C. Nairn, in University. 9870

**CITY OF LONDON
POLYTECHNIC
DEPARTMENT OF
BIOLOGICAL SCIENCES
Laboratory Superintendent—
Technician Grade 8(c)**

Applications are invited for the above post. The department runs both full-time and part-time courses at undergraduate and undergraduate level as well as having an active research programme.

Minimum qualifications required—N.C./D. or equivalent and at least 3 years' relevant experience.

Salary: £5,214 to £5,625 inclusive of London Weighting.

Application forms, which should be returned within two weeks of the appearance of this advertisement, together with the job description, can be obtained from the Secretary, Department of Biological Sciences, City of London Polytechnic, Old Castle Street, London E1 7NT. 9809(A)

**UNIVERSITY OF ABERDEEN
LECTURESHIP
IN DEPARTMENT
OF ANATOMY**

Applications are invited for the above post which will become vacant March 31, 1979. Candidates may have either medical or scientific qualifications and will be expected to, or to become, competent in teaching gross and microscopic anatomy to medical and science students. While area of research is excluded, candidates with interests in growth studies (human and/or experimental), endocrinology, neurobiology or cell biology will be especially welcome.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by March 23, 1979. 9842(A)

**UNIVERSITY OF
MANCHESTER
DEPARTMENTS OF
SURGERY AND PATHOLOGY
POSTDOCTORAL
IMMUNOLOGIST**

Required with experience in the techniques of Cellular Immunology as applied to patients. The post is for one year initially, but renewable. The objective is to study the nature of the immune deficit in injured and malnourished patients. A full-time technician in Immunology and adequate laboratory facilities are available for the project. Salary scale for Research Officer with starting point up to £5,604 per annum. Enquiries to Professor L. Ford, Department of Pathology, Oxford Building, Oxford Road, or Professor M. Irving, Department of Surgery, Hope Hospital, Eccles Old Road, Salford M5 8HD. Applications to Professor Ford by March 15. 9814(A)

**UNIVERSITY OF
NOTTINGHAM
DEPARTMENT OF
PHARMACY
LECTURERS IN
PHARMACEUTICS**

Applications are invited from Pharmacy Graduates for a Lectureship in Pharmaceutics. Experience in Physical Pharmaceutics or Pharmaceutical Technology would be considered an advantage.

The salary will be within the range £883 to £7,754 per annum. Further particulars and forms of application, returnable not later than March 19, 1979, from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD. Ref. 660. 9815(A)

The Daresbury Laboratory has a vacancy for a

COMPUTATIONAL SCIENTIST

to develop the theory of the electronic structure of surfaces and their scattering of electrons and photons, in collaboration with a group of scientists from various institutions: the universities of Coleraine, Leicester, Liverpool, Warwick and York, and the Daresbury Laboratory, all being involved in the collaboration.

The post will be based in the computational science group at Daresbury but will involve occasional visits to the other centres. A strong interest in the interaction between computational theory and the experimental results being obtained in LEED, photoemission from solids and EXAFS will be expected. Applicants should possess a Ph.D degree, preferably in the theory of the solid state, or expect to obtain one during 1979.

An IBM 370/165 computer is installed at the Laboratory providing comprehensive facilities. The laboratory also provides two central facilities for the universities: a purpose-built X-ray and ultra-violet source and a 30MV tandem Van de Graaff to be used for nuclear structure experiments.

Appointments will be made at salaries between £3,695 and £6,216 depending on age, ability and experience. Posts are normally available for a fixed term of 3 years and are superannuable.

Closing date: 1st April 1979.

For further information please write to or telephone the head of the theory group, Dr. J. B. Pendry (Tel. No. (0925) 65000, Extension 223). Applications, from either sex, should be sent together with curriculum vitae and the addresses of two referees, quoting reference number DL/654 to

The Personnel Officer

DARESBUURY LABORATORY Science Research Council Daresbury, Warrington WA4 4AD

9823(A)

**UNIVERSITÄT
KAISERSLAUTERN**

Im Fachbereich Biologie ist folgende Stelle zu besetzen:

**PROFESSOR (C 4) FÜR
BIOTECHNOLOGIE**

Bewerber sollen in der Lage sein, biologische und biochemische Erkenntnisse in praktisch verwertbare Techniken umzusetzen; daher kommen hauptsächlich Arbeitsgebiete aus der angewandten Mikrobiologie in Frage. Habilitation oder entsprechende fachliche Qualifikation ist Voraussetzung. Die Bereitschaft zur Zusammenarbeit mit den vorhandenen biologischen Arbeitsgruppen und den Fachbereichen Chemie, Maschinenwesen und Elektrotechnik wird vorausgesetzt. Neben einer Beteiligung an der Grundausbildung der Diplombiologen und Lebensmittelchemiker soll der Bewerber bei der Ausarbeitung einer Studienrichtung für Biotechnologie massgeblich mitwirken.

Bewerbungen sind mit den üblichen Unterlagen (Lebenslauf, Wissenschaftlicher Werdegang, Forschungsziele, Schriftenverzeichnis, bisher durchgeführte Lehrveranstaltungen) bis zum 15. Juni 1979 zu richten an das Dekanat des Fachbereichs Biologie, Universität Kaiserslautern, Postfach 3049, 6750 Kaiserslautern.

9908(A)

**SHEFFIELD AREA HEALTH AUTHORITY (TEACHING)
SOUTHERN DISTRICT (TEACHING)**

**GROUP DEPARTMENT OF HAEMATOLOGY
NON-MEDICAL SCIENTIFIC OFFICER
(Basic Grade)**

Applications are invited for the above post from candidates possessing an appropriate 1st or 2nd class honours degree in a biological science. The successful applicant will be required to work in the hospitals' Blood Transfusion Laboratories, the main one of which is in the new Hallamshire Hospital. Previous transfusion experience is not required but an interest in hospital work is necessary.

Whitley Council Terms and Conditions of Service apply. Salary Scale (Probationer—new entrants to the National Health Service) £3,486 to £4,275 per annum.

(Post-Probationer—applicants with at least 2 years National Health Service experience) £3,793 to £4,899 per annum.

Candidates wishing to view the Laboratories should telephone Mrs M. S. Lepp, Principal Non-Medical Scientific Officer, Royal Infirmary, Sheffield S6 3DA (Tel: 0742 20977, ext. 400).

Applications stating age, qualifications, experience and the names and addresses of two referees to:

District Personnel Officer,
B Floor, Hallamshire Hospital,
Glossop Road,
Sheffield S10 2JF

by March 12, 1979.

**The International
Atomic Energy Agency**

seeks

**HEAD FOR THE INTERNATIONAL LABORATORY
OF MARINE RADIOACTIVITY IN MONACO**

He should be a Senior Scientist (10-15 years' experience) with knowledge of the oceans, particularly radioactivity. Duties include administration of the Laboratory and responsibility for scientific programme.

Emoluments US\$ 47,000 per annum, tax-free. Additional allowances if married. Travel and removal expenses paid. Six weeks' annual leave. Initial contract two years. Send curriculum vitae under VN 16/79 to IAEA, Division of Personnel, PO Box 590, Vienna, Austria. 9862(A)

DUNDEE COLLEGE OF TECHNOLOGY

Department of Molecular & Life Sciences

**SENIOR LECTURESHIP IN MAMMALIAN
PHYSIOLOGY**

Applicants should have an honours degree and a higher degree in mammalian physiology, together with suitable research or industrial experience. The person appointed will be required to make a major contribution to the teaching of animal physiology in degree, HND and HNC courses, he/she will also be expected to make a substantial contribution to course development, research, staff development and departmental administration.

Salary on the scale £7,155 to £7,962 (bar) to £9,042 with initial placing dependent upon approved prior experience. Financial assistance towards the cost of removal expenses may be payable.

Further particulars and application form obtainable from the Administrative Assistant (Establishment), Dundee College of Technology, Bell Street, Dundee DD1 1HG, to whom completed application forms should be returned by March 16, 1979. 9827(A)

**THE CITY UNIVERSITY
DEPARTMENT OF
CHEMISTRY
LECTURER**

Applications are invited for a Lectureship tenable in the above Department from April 1, 1979 or as soon as possible thereafter. Candidates should be INORGANIC CHEMISTS with an enthusiasm for teaching and with active research interests.

Salary will be on the scale £3,883 to £7,754 per annum (under review) plus £450 per annum London Allowance.

Application forms and further details are available from the Deputy Academic Registrar, The City University, Northampton Square, London EC1V 0HB, telephone 01-253 4399, ext. 338. Please quote reference C/232/N. Closing date March 31, 1979.

9824(A)

**TECHNICIAN/RESEARCH
OFFICER**

Required to assist in research into the control of animal cell division. Main duties include cell culture work and performance of experiments concerned with elucidating the mechanisms by which cell division is controlled. Techniques used include ³H-thymidine autoradiography, time-lapse microcinematography, cell-cell fusion.

HNC/Degree required. Salary range £3,261 to £4,902 plus L.W. For application form telephone Mrs Nelson, Imperial Cancer Research Fund, Lincoln's Inn Fields, WC2 on 01-242 0200, ext. 305. 9840(A)

**UNIVERSITY OF
CALIFORNIA AT DAVIS
ZOOLOGY DEPARTMENT
POSTDOCTORAL
RESEARCH ASSOCIATE**

A postdoctoral research position is available for a cellular physiologist to investigate both transcellular ion currents and intracellular ion concentration changes during the activation and early development of vertebrate eggs. Both the extracellular vibrating probe (J. Cell Biol. 63: 614) and recessed-tip intracellular ion-specific microelectrode techniques are being used in this research. Some experience with electrophysiology is desired. This appointment will be for two to three years. Salary: \$11,000/yr. Closing Date: April 1, 1979.

Send résumé and names of three references to: Dr. R. Nuccitelli, Zoology Department, University of California, Davis, CA, 95616, U.S.A. Equal Opportunity/Affirmative Action Employer. 9875(A)

BIRZEIT UNIVERSITY

An independent Arab University in the Israeli-occupied West Bank of Jordan has the following faculty openings for the academic year 1979/1980: BIOLOGY—BIOCHEMISTRY, CHEMISTRY (PHYSICAL, INORGANIC, ORGANIC), MATHEMATICS (ALGEBRA, ANALYSIS, MATHEMATICAL STATISTICS), PHYSICS (Experimental and Theoretical). English is the basic language of instruction and candidates should have a Ph.D. preferably or a master's degree with experience. Starting annual salary for Ph.D. is 2,700 Jordanian Dinars (current exchange rate 1 JD equals about £17). Optional summer teaching extra fringe benefits include Relocation allowance (15 per cent of salary). Transportation also provided. All applications should be addressed to Dean of the Faculty of Science, Birzeit University, Birzeit, West Bank Via-Israel. 9909(A)

**THE QUEEN'S
UNIVERSITY OF BELFAST
LECTURESHIP
IN BIOCHEMISTRY**

A lectureship in the Department of Biochemistry is available from October 1, 1979, or such other date as may be arranged. The lecturer will be expected to teach at various levels and to engage in research, preferably collaborative, in fields already active in the Department, details of which are set out in a departmental prospectus which is available. Initial placing, which will depend on age, experience and qualifications, will be made at one of the first three points on the scale for lecturers (effective October 1, 1978 but subject to further review). £3,385, £4,134, £4,383 rising to £7,755 with contributory pension rights under the FSSU/USS. The appointment will be subject to a period of probation of up to three years. Further particulars are available from the Personnel Officer, The Queen's University of Belfast, Belfast BT7 1NN, Northern Ireland. Closing date: April 16, 1979. (Please quote Ref. 79/N.) 9887(A)

The Research Organisation of Internationally recognised Europe Pharmaceutical Group located in Pa requires a

**TECHNICAL
RESEARCH OFFICER**

The high success rate and rapid growth of this pharmaceutical group is related to the quality of people they employ and their continued commitment to research and development.

To strengthen the research effort the research organisation requires professional and highly motivated scientists who will be responsible for:

- Advancing on the implementation of the GLP standards within research and within a proposed new research centre.
- Assisting with the planning and organisation of research projects.
- Organising the collation and storage of research data.

Applicants can be either male or female and should be a graduate in biological sciences. It is essential that the candidate should have experience of the pharmaceutical industry.

A realistic salary can be expected and relocation assistance will be available together with other financial benefits.

All applications will be treated with the strictest confidence and should be sent to 'Nature' who will forward. 9895(A)

MEDICAL RESEARCH COUNCIL

MRC PNEUMOCONIOSIS UNIT
Llandough Hospital, Penarth,
South Glamorgan, CF6 1XW

Applications are invited for post in statistical section of this Unit. The work involves statistical counselling and the design and analysis of experiments in the different fields of activity of the Unit—clinical medicine, physiology, radiology, pathology, immunology, physics, biochemistry, demography, and the extraction of information from data, already existing, in industry and elsewhere, bearing on occupational lung diseases.

Applicants could be recent graduates in mathematical statistics, graduates with some years experience in medical statistics, or graduates wishing to engage to medical statistics from some other field of biometry.

Further details may be had on application to the Director, at above from. 9838(A)

COMMONWEALTH AGRICULTURAL BUREAUX Vacancy for SCIENTIFIC INFORMATION OFFICER

at the
Commonwealth Bureau of Plant
Breeding and Genetics
Department of Applied Biology
Cambridge CB2 3DX

ties include scanning the world literature dealing with the breeding, genetics and cytology of economic plants, preparing abstracts for publication in *Plant Breeding Abstracts*, and answering enquiries within this field. A degree either in biology, agriculture or genetics or in human is required. Applicants coming with scientific and linguistic aptitudes will receive prior consideration. Capacity to read foreign languages other than German will count as additional qualification. Ability to write good English is essential.

Salary. The salary is in the scale £39 to £5,448 p.a. plus a compulsory allowance (taxable but not pensionable) of 3.3% of basic salary to offset personal contribution to pension scheme. Starting salary according to qualifications and experience. Promotion to higher scales on merit.

Application forms and full particulars from: Executive Director, Commonwealth Agricultural Bureaux, Rothamsted House, Farnham Royal, Bucks SL2 3BN.

Closing date for applications: March 1979 9839(A)

NEUROPATHOLOGIST/ PHYSIOLOGIST/BIOLOGIST

required by the Biology section of the Medical Research Council Cyclotron Unit. The successful applicant will be a group investigating responses of small tissues in animals which are relevant in the treatment of cancer. Studies will include effects of both ultraviolet and X-rays and certain adjunct treatments used in radiotherapy. The post will be concerned primarily with damage to nervous tissue but may extend to other tissues. The applicant must have a First or Upper Second Class degree in an appropriate subject and at least 3 years' postgraduate research experience or a degree in medical or veterinary sciences relevant experience is desirable but not essential. The post is a three year term appointment. Salary, according to age and experience, in the range £6,081 to £6,530 (inclusive of pay supplements and London Weighting), plus 5 weeks annual leave. Please write, giving qualifications and curriculum vitae, to:

Miss A. Pires, MRC Cyclotron Unit, Hammersmith Hospital, Duane Road, London W12 0HS Tel: 01-743 4394, ext. 103. 9892(A)

PRECEPTOR Harvard University

Applications are invited for the position of preceptor to organise and supervise laboratories for two introductory courses (introductory organismic and evolutionary biology, comparative animal physiology and anatomy). The Ph.D. or equivalent research/teaching experience is preferred. This position is renewable on an annual basis for 5-8 years. Starting date: July 1, 1979. Applications should be addressed to the Chairman's Office, Department of Biology, Harvard University, Cambridge, Mass. 02138. Harvard is an Equal Opportunity/Affirmative Action Employer. 9846(A)

THE POLYTECHNIC OF CENTRAL LONDON DIVISION OF SCIENCE LECTURER II IN PLANT ECOLOGY

Salary: £4,575 to £7,032 inclusive of London Allowance. Applicants should be Honours graduates in Botany, Biology or Environmental Science with at least a Ph.D. or equivalent research experience in Quantitative Plant Ecology. The successful candidate will be expected to teach aspects of Ecology and Plant Diversity at Honours Degree and postgraduate level and to participate in research.

Application form and further details from the Establishment Officer, PCL, 309 Regent Street, London W1R 8AL (01-580 2020 ext 212).

Closing date: Three weeks after the appearance of the advertisement 9850(A)

UNIVERSITY OF CALIFORNIA DEPARTMENT OF VITICULTURE AND ENOLOGY

The Maynard A. Amerine Professorship

An Endowed Chair From
The Ernest Gallo Foundation
Applications are now invited for the Maynard A. Amerine Professorship. Applicants should have made research contributions of significance at the professional level in fields that include or are pertinent to enology, viticulture, or the fermentation sciences. The appointee will be expected to contribute to both undergraduate and graduate instruction and to provide intellectual leadership in the Department, the College, and the Davis Campus.

The formal appointment will be a permanent position as a tenured member of the Department of Viticulture and Enology at one of the higher steps of the rank of full professor.

Applications, in the form of a letter describing research and teaching interests and background, together with a curriculum vitae and three letters of recommendation, should be submitted by May 15, 1979, to:

The Chair
Search Committee for the Amerine
Professorship c/o College of Agricultural and Environmental
Sciences
228 Mink Hall
University of California
Davis, CA 95616

The University of California is an affirmative-action/equal-opportunity employer. 9853(A)

POSTDOCTORAL POSITION

for 2 years available immediately. Studies on gene expression of enveloped animal viruses, vesicular stomatitis and Rous sarcoma, viral membrane biogenesis and morphogenesis (P.N.A.S. 74, 1516, 75, 715, 76, 570). Starting salary \$11,600. Ph.D. in biochemistry, molecular biology or microbiology preferred. Send résumé and three references to Dr H.P. Ghosh, Professor, Department of Biochemistry, McMaster University, Hamilton, Ontario L8S 4J9 Canada. 9854(A)

The ICI Corporate Laboratory, situated at Runcorn, Cheshire, has the following vacancies for research scientists:—

BIOCHEMIST/ PLANT PHYSIOLOGIST

Two scientists are required to join a small team within the Bioscience Group, investigating aspects of the regulation of cereal development, with a view to the development of chemicals with novel plant growth regulatory activity. Applicants should possess a degree or equivalent qualification in a subject which includes knowledge of biochemistry or plant physiology. Practical laboratory experience will be an advantage. (Ref. BS1).

THEORETICAL CHEMIST/ PHYSICIST

A research scientist is required to join a small theoretical group within the Corporate Laboratory, to investigate aspects of solid state physics. A PhD in some branch of theoretical physics or chemistry, together with computational experience is essential. (Ref. PT1).

If you are interested in either of these vacancies, please write, not later than March 9th, quoting reference number, and including a full curriculum vitae, to:

Miss S E Bird
Personnel Officer
ICI Corporate Laboratory
PO Box 11
The Heath
RUNCORN Cheshire

9830(A)

WELLCOME MUSEUM HISTORY OF MEDICINE

Assistant Keeper

to take part in the transfer of objects (illustrating the history of medicine) from the Wellcome Trustees to the Science Museum and to be responsible for maintaining and developing a number of collections. This involves seeking new material, historical research, answering enquiries, and general administration. An important part of the duties includes working on particular aspects of setting up new permanent galleries and documentation of the objects.

Candidates must have a degree with first or second class honours, or an equivalent qualification, in a relevant subject and the ability to explain medical and scientific matters clearly to the lay public. Experience in museum work at a high level, medical or related qualifications/experience, and/or knowledge of the history of medicine, advantageous.

SALARY: as AK I £6855—£8820 or AK II £3575—£5305. Level of appointment and starting salary according to age, qualifications and experience. Non-contributory pension scheme.

For full details and an application form (to be returned by 30 March 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants., RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote G(12)382. 9833(A)

SCIENCE MUSEUM

LEICESTER UNIVERSITY

FACULTY OF SCIENCE

Chair of Physics

Applications are invited for an additional Chair of Physics tenable from October 1, 1979 or an agreed later date. Candidates should be experienced in some branch of experimental physics.

Further particulars from the Registrar to whom applications should be sent by April 21, 1979. Candidates in the U.K. should submit 15 copies of their application (overseas candidates may submit one copy). 9867(A)

RESEARCH OFFICER/ TECHNICIAN

required by the Medical Research Council Cyclotron Unit at Hammer-smith Hospital. The work will consist mainly of the study of subcellular changes in cell and tissue systems after exposure to radiation and other toxic hazards. The aim is to gain a fuller understanding of post-treatment changes in normal and malignant tissues. Previous experience of biochemical and/or cell culture techniques would be advantageous. Candidates should possess a degree or equivalent qualification in a relevant discipline. Salary, according to age and experience, in the range £3,615 to £5,256 (inclusive of London Weighting).

Please write, giving qualifications and curriculum vitae, to: Miss A. Pires, MRC Cyclotron Unit, Hammer-smith Hospital, Duane Road, London W12 0HS. 9893(A)

THE INSTITUTE OF CHEMISTRY

invites applications for TWO FACULTY POSITIONS

in organic geochemistry. Applicants should have the Ph.D., and research interest in petroleum geochemistry. The salary will be commensurate with experience and qualifications (minimum: \$22,000).

Applications including a curriculum vitae and the names of three references should be addressed to:

Dr Carlos López Eyzaguirre
Instituto de Química
Facultad de Ciencias
Universidad Central de Venezuela
Apartado 10098
Caracas-Venezuela

9905(A)

WELSH NATIONAL SCHOOL OF MEDICINE (University of Wales) DEPARTMENT OF MEDICAL BIOCHEMISTRY

RESEARCH OFFICER

required for a DHSS-funded appointment (renewable annually for up to 3 years) in the above Department at Health Park, Cardiff.

The project involves the development of chemiluminescent compounds as alternative labels to radioactive iodine in immunoassay. The aim is to establish clinically useful methods for measuring a variety of peptides and small molecules using luminescence. Candidates should have a degree in Biochemistry or Chemistry and the position would be suitable for someone wishing to study for a higher degree. Starting salary up to £3,384 per annum.

Further particulars (quoting ref. No. C38/4/26) from the Registrar and Secretary, Welsh National School of Medicine, Health Park, Cardiff, CF4 4XN to whom applications should be submitted by March 31, 1979. 9859(A)

QUEEN MARY COLLEGE University of London PHYSICS DEPARTMENT

Applications are invited for appointment as

LECTURER

from October 1. Preference may be given to candidates with research interests in Experimental High Energy Physics or the application of physics to the Design and Development of Techniques of measurement or detection. Salary scale £3,975 to £8,250 per annum (under review) plus £450 London Allowance. Further details and application forms available from The Registrar (N), Queen Mary College, Mile End Road, London E1 4NS, to be returned by April 11. 9808(A)

CHAIRPERSON, PROFESSOR OF CHEMIS DEPARTMENT OF CHEMIS

State University of New York Albany—Applications are invited for this position to start on September 1979 or as soon thereafter as possible. The Department of Chemistry commitment to continuing development of outstanding programs search and teaching and seeks a person to provide leadership in areas and to guide the future of the department. The applicant should be a chemist of senior with an established reputation search and interest in teaching administration. Each applicant send a resume and the names of three references to: J. A. Z. Chairman, Search Committee, Department of Chemistry, State University of New York at Albany, Albany, New York 12222. Applications should be completed before March 30, 1979. EO/AA employer. 974

THE UNIVERSITY OF MANCHESTER EXPERIMENTAL OFFICE DEPARTMENT OF PHARMACY

The person appointed will be responsible for the development co-ordination of analytical techniques in research dealing with pharmacokinetics, drug metabolism and pharmacology. The techniques primarily involve the use of chromatography, spectroscopy and radioactivity. Successful candidate will also help and run kinetic experiments on animals and man, and help in assessing the data using computer techniques. Applicants must be able in either chemistry, biochemistry or a related science, with a minimum of two years' relevant experience. Initial salary in the range £3,384 to £5,604, depending on U.S.S. Particular application forms (returnable by 20) from the Registrar, The University, Manchester M13 9PL. Quote 38/79/N. 981

UNIVERSITY OF NEWCASTLE UPON TYNE THE MEDICAL SCHOOL APPOINTMENT OF LECTURER IN PHYSIOLOGY

Applications are invited for a Lectureship in Physiology (Medical Non-Medical) in the Department of Physiology. The Department responsible for the teaching of PHYSIOLOGY & PHYSIOLOGICAL BIOCHEMISTRY to Medical, and Pure Science students. Appointment will be from the date on or after October 1, which may be agreed. Ample opportunity exists for a medically qualified person to engage in interdisciplinary clinical research and teaching.

The appointment will be made on the Lecturers' Pre-Clinical Grade (£5,129 to £7,754) or Lecturers' Pre-Clinical Higher (£7,268 to £8,257) in the case of a medically qualified person. In the case of a person not medically qualified, appointment will be to the Lecturers' Non-Medical Grade (£3,883 to £5,129). The appointment will be made on a suitable point on these scales according to age, qualifications and experience. Membership of the appropriate University superannuation scheme will be required.

Further particulars may be obtained from the Senior Assistant Registrar, The University, 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU to whom applications (three copies) together with the names and addresses of three referees, should be sent not later than April 2, 1979. quote reference N. 981

LIVERPOOL UNIVERSITY MEDICAL SCHOOL SENIOR RESEARCH ASSISTANT

join a group working on the development of new probes for identifying illular antigens in the electronmicroscope. The post is funded by a 3-year R.C. grant and is suitable for someone with a chemical/biochemical background wishing to gain experience in a cell biological area. Applicants could have a Ph.D. in biochemistry or a related subject.

The initial salary will be in a range of £5,129 per annum. Applications, together with the names of two referees should be received not later than March 23, 1979, by The Registrar, The University, P.O. Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained. Note Ref: RV/505/N. 9866(A)

POSTDOCTORAL RESEARCH ASSOCIATE POSITION

To study role of poly(adenosine phosphoribose) synthesis in eukaryotic DNA repair processes. Experience with DNA repair processes. Experience with DNA repair, nucleic acid and rromatin chemistry desirable. Send curriculum vitae and references to Dr A. Berger, Hematology-Oncology Division, Jewish Hospital, Washington University School of Medicine, 216 S. ngshighway, St. Louis, Missouri, 110.

Equal Opportunity Employer. 9860(A)

CANCER CHEMOTHERAPY
Postdoctoral Research Training offered jointly by the Departments of Medicine, Mendelsohn, M.D. and S. B. Holl, M.D.) and Chemistry (The Athletic Mouse Research Center, N. O. aplan, Ph.D.), University of California, San Diego. The successful candidate (M.D. or Ph.D.) will be able to study various chemotherapies on human tumor lines in athymic mice and correlate them with clinical cases at the University Hospital. For the next year the annual stipend ranging from \$10,000 to \$13,200 commensurate with experience is available from training grant. The Fellow will be expected to apply for own support for subsequent two years. Closing date for application is April 30, 1979; appointment date is August 1, 1979. Apply to: Dr. N. O. Kaplan, Q-058, University of California, San Diego, La Jolla, CA 92093. The University of California is an Affirmative Action employer. 9861(A)

UNIVERSITY OF ABERDEEN TECHNICIAN (Grade 5)

required to look after the Electron microscope Unit in the Department of Botany to maintain, operate and repair specimens for a Philips EM301 transmission electron microscope and Cambridge Instruments S600 scanning electron microscope. The unit, which is used for teaching and research, is well equipped with ancillary apparatus including a freeze-drying machine, a sputter-coater and critical point drier and has its own photographic darkroom. Applicants should hold an HNC (or equivalent qualification) and should have had considerable experience in electron microscopy or in photography and electronics.

For suitably-qualified candidate, salary on scale £3,186 to £3,720 (under review).

Applications from recent graduates interested in training in electron microscopy will be considered for appointment against this post; salary for a candidate during initial training period would be on scale £2,346 to £499 (under review).

Applications giving date of birth, educational qualifications and previous experience should reach the Secretary, University Office, Regent Walk, Aberdeen, AB9 1FX, by March 22, 1979. Please quote Ref. No. 50/79. 9873(A)

UNIVERSITY OF ABERDEEN DEPARTMENT OF MEDICINE POSTDOCTORAL RESEARCH FELLOW

Applications for the above post are invited from biological scientists with a knowledge of transplantation immunology. The successful applicant will join a team investigating the role of gene products of the major histocompatibility complex, especially HLA-D and HLA-DR matching, in renal allograft survival.

Commencing salary will be £4,382 per annum on the Range 1A Scale for Research and Analogous Staff, plus U.S.S. The post is grant supported and is available for three years from September 1, 1979, or from a suitable date to be negotiated.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by March 23, 1979. 9841(A)

UNIVERSITY OF LONDON CHAIR OF BOTANY tenable at Imperial College of Science and Technology

The Senate invites applications for the above Chair, tenable in the Department of Botany and Plant Technology.

The present strengths of the Department lie mainly in plant physiology, plant pathology and timber technology. Fields that could now with advantage be strengthened include ecology or physiological ecology, all areas of genetics, and microbiology. Candidates with interests in other fields may also be considered.

The Professor of Botany will be eligible for appointment as Head of the Department of Botany and Plant Technology when Professor A. J. Rutter retires on August 31, 1979.

Applications (10 copies) must be received not later than March 19, 1979, by the Academic Registrar (N), University of London, Malet Street, London WC1E 7HU, from whom further particulars should first be obtained. 9899(A)

MEDICAL LABORATORY SCIENTIFIC OFFICER (OR JUNIOR)

required for varied endocrine analytical work in Department of Gynaecology (Biochemistry Laboratory). HNC standard needed or "A" level chemistry for junior post. Apply giving age and details of qualifications and experience to Dr. M. G. Brush, St. Thomas's Hospital Medical School, London, SE1 7EH. 9843(A)

AGRICULTURAL RESEARCH COUNCIL INSTITUTE OF ANIMAL PHYSIOLOGY

Babraham, Cambridge, CB2 4AT

Applications are invited for a post, financed by the M.R.C. for 3 years commencing October 1, 1979. This project involves studies of the transport, metabolism and secretion of vasoactive agents using endothelial and smooth muscle cells in culture as well as isolated vascular preparations. It forms part of an integrated programme of vascular physiology, under the supervision of Dr J. L. Gordon, in the Department of Cell Biology. Candidates must have a good honours degree in physiology, biochemistry or a related subject, and experience with any of the above techniques would be advantageous. Preference will be given to candidates possessing a Ph.D. or equivalent. Salary in scale £4,101 to £5,448 or £5,154 to £6,898, depending on experience. Applications, including C. V. and names of two referees, should be sent as soon as possible to the Secretary of the Institute, quoting Ref. J. L. G. Closing date April 5, 1979. 9844(A)

Royal Botanic Gardens, Kew

Botanists/ Biologists

The Gardens, while primarily a scientific institution, also provide an important public amenity. The scientific work is concerned with the classification, growth, structure and uses of plants, utilising the rich collections of preserved material in the Herbarium and Museums and the unique collection of living plants in the Gardens.

Anatomical Investigations

This post is in the Jodrell Laboratory which provides facilities for anatomical, cytological and physiological research. The botanist/biologist appointed will join a team working on systematic and experimental plant anatomy. This will involve identifying plant fragments and organs, developing new techniques and providing a technical advice service to visiting research workers. The work will involve the use of optical and scanning electron microscopes.

Candidates, normally aged under 27, should have an Honours Degree or equivalent in a discipline which has included a specialist study of botany. An interest in natural history and geography would be an advantage.

Reference: SB/18/AH.

International Conservation Work

The Conservation Unit works in close co-operation with the Threatened Plants Committee of the International Union for Conservation of Nature and Natural Resources. The botanist/biologist appointed will collate national and international information on threatened plants and floras with a view to formulating conservation schemes. In addition, the successful candidate will assist with Kew's work of advising the public on plant conservation.

Candidates, normally aged under 27, should have a good Honours Degree or equivalent in an appropriate discipline which has included a specialised study of both botany and geography. An interest in nature conservation and the diversity of the plant kingdom is highly desirable. Reference: SB/19/AH.

Appointment as Scientific Officer (£3110-£4690) with starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 30 March 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours).

Please quote appropriate reference.

Group**
CIVIL SERVICE

9871(A)

UNIVERSITY OF CRETE

The Departments of Mathematics and Physics are having openings for visiting appointments at all ranks. Greek speaking mathematicians and physicists are invited to apply. Applications for regular appointments will be formally solicited soon.

All correspondence including letters of recommendation should be sent by the end of April 1979: to Ms Sophia Fotiti, University of Crete, Solonos 71, Athens 143, Greece. 9851(A)

Research Microbiologist

Guinness is seeking a graduate microbiologist to join the present research team in its Dublin Brewery.

The successful candidate will have proven ability in either academic or industrial research. Detailed knowledge of fermentation technology is highly desirable. He or she will be expected to carry out independent work in problem solving and in the application of

innovative approaches to fermentation microbiology.

An attractive starting salary will be negotiable, based on experience and qualifications. Conditions of service are excellent and include four-and-a-half weeks' annual vacation, non-contributory pension, profit-sharing scheme and assistance with relocation expenses.

Please write giving full details of age, qualifications and experience to:

Dr. R.B. Gilliland,
(Ref. MI 79)
Manager, Research & Development,
Arthur Guinness Son & Co. (Dublin) Ltd.
St. James's Gate, Dublin 8.

GUINNESS

9825(A)

UNIVERSITY OF DAR ES SALAAM—TANZANIA

Applications are invited for the following posts in the
DEPARTMENT OF ZOOLOGY

LECTURER/SENIOR LECTURER IN ZOOLOGY
(ENTOMOLOGY/PARASITOLOGY)

Applicants should hold a Ph.D. with research and several years of teaching experience in Entomology and Parasitology. Appointee will be required to organise undergraduate course in applied entomology and animal parasitology and to teach and supervise research in his/her subject area at postgraduate level; to organise and carry out research in Entomology and Parasitology. Further, he/she will be expected to work in collaboration with other members of the Department in an integrated research programme.

LECTURER/SENIOR LECTURER IN WILDLIFE
ECOLOGY AND MANAGEMENT
(POPULATION ECOLOGY)

Applicants should hold a Ph.D. with research and teaching experience in Population Ecology. Appointee will be required to organise undergraduate courses in Animal population ecology and to teach and to supervise research in his/her subject area at postgraduate level; to plan and carry out research in Animal ecology relevant to Tanzania. Further, he/she will be expected to work in collaboration with other members of the Department in an integrated research programme.

SALARY SCALES (salaries exclusive of 50 per cent expatriation allowance). Senior Lecturer ET1,980 to ET2,480 per annum. Lecturer ET1,620 to ET1,980 per annum (ET1 equals £1 22 sterling). The British Government may supplement salaries in range £4,356 to £4,782 per annum (sterling) for married appointees and £2,754 to £3,018 (sterling) for single appointees (reviewed annually and normally free of tax) and provide children's education allowances and holiday visit passages. Family passages; F.S.S.U. biennial overseas leave. Detailed applications (two copies) with curriculum vitae and naming three referees to be sent direct to Chief Academic Officer, University of Dar es Salaam, P.O. Box 35091, Dar es Salaam, Tanzania, by April 8, 1979. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 9857(A)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF HISTOLOGY AND CELL BIOLOGY (MEDICAL) TECHNICIAN

To join group using immunological methods to study a variety of cellular activities. Experience in methods for culturing lymphocytes or radioimmunoassay an advantage but not essential.

Salary in a range up to £2,880 p.a. (under review). Application forms may be obtained from The Registrar, The University, P.O. Box 147, Liverpool, L69 3BX. Quote Ref: RV/509/N. 9880(A)

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF BIOCHEMISTRY Applications are invited for a post of LECTURER IN BIOCHEMISTRY

tenable from October 1979

The successful candidate will be expected to be interested in mammalian and medical biochemistry and to participate in teaching and research in these areas. A medical degree would be an advantage although is not essential. The Department provides courses for science, medical and dental undergraduates. Excellent facilities are available for most types of biochemical research.

Salary within the range £3,883 to £7,754 p.a. (plus USS), depending on age, qualifications and experience.

Applications (2 copies) naming 3 referees should be sent by March 30, 1979 to Miss L. R. Heyes, Senate Registry, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, from whom further particulars may be obtained. 9779(A)

THE ANIMAL VIRUS RESEARCH INSTITUTE PIRBRIGHT

Applications are invited for a person to work with a group engaged on the structure and replication of animal viruses. The successful candidate will be expected to work on the proteins of the viruses, with the aim of relating structure to antigenic activity. Applicants should have a first/second class honours degree in Biochemistry or related subject, with at least 2 years post graduate research experience. The post is in the HSO grade (£4,101 to £5,448). House available for suitable married applicant. Non-contributor superannuation scheme.

Application forms and further particulars from the Secretary, The Animal Virus Research Institute, Pirbright Woking, Surrey, GU24 0NF. 9890(A)

UNIVERSITY OF NEWCASTLE UPON TYNE BIOCHEMISTRY RESEARCH DEMONSTRATORSHIP

Applications are invited for a post of DEMONSTRATOR in the Department of BIOCHEMISTRY for candidates who possess, or have submitted for, a Ph.D. in Biochemistry for a period of up to three years tenable as soon as possible. Research projects currently in progress include membrane transport of nucleic acid precursors, acquisition and modification of enzyme conformation, DNA repair and genetic recombination, triglyceride and lipoprotein metabolism, enzymology of resistance to antibiotics and biotransformation. Duties will also include teaching (approx. 2 hours per term) by lectures, tutorials and practical classes.

Salary will be at an appropriate point on the Grade IB (bar) scale £3,384 to £4,882 per annum, according to age, qualifications and experience. Membership of the appropriate University superannuation scheme will be required.

Further particulars may be obtained from the Senior Assistant Registrar, The University, 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU to whom applications (two copies), together with the names and addresses of three referees, should be lodged not later than March 31, 1979. Please quote reference N. 9813(A)

UNIVERSITY COLLEGE, BOTSWANA

Applications are invited for the post of LECTURER in ENVIRONMENTAL SCIENCE in the DEPARTMENT OF GEOGRAPHY. The appointee will be expected to organise and teach courses in Hydrology and Soil Science at BSc Part II level. The appointee will assist with the introductory courses in aspects of the physical environment to a wide range of students. He/she will also be encouraged to pursue research in his/her field. Salary scale, P5,652 to P9,492 p.a. (£1 sterling = P1.65). The British Government may supplement salary range £2,478 to £2,724 p.a. (sterling) for married appointee or £924 to £940 p.a. (sterling) for single appointee (reviewed annually and normally free of tax) and provide children's educational allowances and holiday visit passages. Family passages; inducement allowance 30%, gratuity 25% at end of each 2 year tour, biennial overseas leave various allowances. Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent Registrar, University College Botswana, PB 0022, Gaborone, Botswana Southern Africa by April 17, 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road London W1P 0DT. Further details may be obtained from either address. 9884(A)

**ROYAL FREE HOSPITAL
SCHOOL OF MEDICINE
(University of London)
DEPARTMENT OF
BIOCHEMISTRY AND
CHEMISTRY
POSTDOCTORAL
RESEARCH ASSISTANT**

Applications are invited for work with Professor J. A. Lucy on membrane fusion, supported by a research grant for three years from the Medical Research Council. Experience of work with proteins and proteinases would be an advantage.

Commencing salary within range £3,909 to £4,408 plus £430 London allowance.

Further particulars from the School Secretary, R.F.H.S.M., 8 Hunter Street, London WC1N 1BP, tel. 01-57 5385, ext. 54, to whom applications (two copies) with the names of two referees should be submitted as soon as possible, quoting reference MRC. 9812(A).

**THE UNIVERSITY OF
THE WEST INDIES
TRINIDAD**

Applications are invited for the post of LECTURER/ASSISTANT LECTURER in ANALYTICAL CHEMISTRY in the DEPARTMENT OF CHEMISTRY. Salary scales (under review): 1977/78: Lecturer: TT319,071 £29,799 p.a. Assistant Lecturer: TT15,480 to £16,974 p.a. (£1 sterling TT\$4.80). FSSU Unfurnished accommodation if available at 10% or rented at 12½% or housing allowance of 20% of pensionable salary, family passages. Study and Travel Grant. Detailed applications with curriculum vitae and naming three referees should be sent direct to Secretary, U.W.I., St. Augustine, Trinidad as soon as possible. Applicants resident in the UK should also send copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0JT. Further details may be obtained on either address. 9885(A).

**CHELSEA COLLEGE
University of London
BIOPHYSICS**

TECHNICIANS GRADE 4 and GRADE 2B required to assist in research and teaching activities within the Biophysics section of the Basic Medical Sciences Group.

Experience of biophysical, bioengineering and/or biochemical techniques would be an advantage.

Salary scales (under review):
Grade 4 £3,420 to £3,867 per annum inclusive
Grade 2B £2,994 to £3,345 per annum inclusive

Enquiries and application forms from a Secretary, Biophysics Laboratory, Chelsea College, 17a Onslow Gardens, London SW7 3AL. Tel. 01-589 4438. 9882(A).

**THE FEDERAL UNIVERSITY
OF PARÁIBA**

João Pessoa, BRAZIL

FACULTY POSITIONS

in the Chemistry of Natural Products and in Pharmacology

Applications are invited for a number of positions from individuals holding doctoral degree in the above areas. The successful candidates will participate in research and teaching of the course in natural products chemistry and pharmacology.

Salary: US\$20,000 to US\$22,000 as fringe benefits.

Send curriculum vitae, list of publications and names of three referees to Director, Laboratório de Química Farmacológica, Universidade Federal da Paraíba, 58000-João Pessoa-Paraíba-Brazil. 9876(A).

Pharmacologist Gastrology Ware, Herts

An opportunity has arisen in our Pharmacology Department for a graduate pharmacologist/physiologist with experience of the alimentary system.

The vacancy is within the Gastrology Project team which is studying new drugs for treating gastric ulceration. The successful candidate will supervise routine testing of new compounds and conduct basic research into new areas of alimentary function.

Applicants must have spent several years working on the gastro-intestinal tract and should possess a Ph.D. degree. Graduates with comparable experience will also be considered.

This is an immediate vacancy and graduates who will be completing their studies later this year should not apply.

The post carries a competitive starting salary which will reflect the age, experience, and qualifications of the successful candidate. Other benefits include bonus, pension and productivity schemes, extensive sports and social facilities, and where appropriate, assistance with relocation expenses.

Please apply to: Ian Collins, Ph.D., Personnel Manager, Glaxo-Allenburys Research (Ware) Ltd., Ware, Herts. SG12 0DJ. Tel. Ware 3232. 9898(A).

Glaxo-Allenburys Research (Ware) Limited

**MEDICAL RESEARCH
COUNCIL**

Radiobiology Unit, Harwell

**MAMMALIAN GENETICIST
OR CYTOGENETICIST**

A scientist is needed to join a group studying the genetic effects of radiation and other mutagenic agents in mammals. The emphasis is on methods of exploring the sensitivity to mutagens of germ cells of different sexes, developmental stages and species in the intact animal. Formal genetics and cytogenetics relevant to the mutagenesis work are also included. Candidates with experience of genetics of higher organisms, or of handling rodent chromosomes, at either meiotic or mitotic stages, would be at an advantage.

Possible subjects of research include

- comparison of the sensitivity to mutagens of various mammalian species, with particular emphasis on methods of studying chromosome changes in oocytes and early embryos,
- studies of the causes of chromosomal non-disjunction in mammals,
- factors affecting the sensitivity of oocytes to mutagenesis.

There are excellent research facilities. The Unit also includes groups studying cell mutation, cytogenetics, pathology, and effects of radionuclides.

Applicants should hold a relevant good honours degree, with three years' research experience, and preferably a Ph.D. Salary and conditions of service according to M.R.C. non-clinical scientific scales. Hostel accommodation for single, or housing for married, people may be available.

Applications, with curriculum vitae and names of two referees, should be sent to Administrator, M.R.C. Radiobiology Unit, Harwell, Didcot, Oxon. OX11 0RD, from whom further particulars may be obtained. 9733(A).

**UNIVERSITY OF SUSSEX
SCHOOL OF BIOLOGICAL
SCIENCES**

**CYTOGENETICIST/
CELL BIOLOGIST**

Preferably with some postdoctoral experience of current techniques in genetic toxicology using mammalian cells, required to join MRC funded project on assessment of risks associated with pre-natal exposure to mutagens and carcinogens.

The appointment will be made at a starting salary in the range £3,883 to £4,382 p.a. on the Research Fellow 1A scale (under review) with superannuation benefits, and the post is tenable for 3 years. Starting salary dependent on age and experience.

Applications, (including curriculum vitae and details of 2 referees) should be sent to Professor Robin Cole, Developmental Genetics Laboratory, School of Biological Sciences, University of Sussex, Falmer, Brighton BN1 9QG, as soon as possible. 9880(A).

**UNIVERSITY OF OXFORD
DEPARTMENT OF
PHYSICS**

Clarendon Laboratory

SURFACE PHYSICS

ELECTRON MICROSCOPY

A Physicist with experience of electron microscopy is required to work as a postdoctoral research officer in a group concerned with studies of the physics of surfaces, particularly their mechanical and chemical properties, using both scanning and transmission electron microscopy. The group receives substantial support from industry, with which it has close links. The post is for a period of three years and involves a limited amount of demonstrating. Salary scale £3,384 to £4,466, under review, starting point according to age, e.g. £3,883 at age 24.

Application, with curriculum vitae and names of two referees, should be sent to Dr J. Wilks, Clarendon Laboratory, Oxford OX1 3PU, from whom further details may be obtained. 9836(A).

**MEDICAL RESEARCH COUNCIL
Clinical and Population Cytogenetics Unit
Edinburgh
MOLECULAR OR CELL BIOLOGIST**

A vacancy exists for a molecular or cell biologist to work with a small team studying the molecular organisation and function of human chromosomes. One area of interest involves the use of restriction enzymes in the study of DNA composition and variation in man and experience with relevant techniques, or in the handling of cultured mammalian cells and chromosomes, would be an advantage, but not essential. Candidates should have a Ph.D. or equivalent and the appointment will be made at an appropriate level on Medical Research Council scientific scales. Applications, including names of two referees, should be sent to the Administrative Officer, M.R.C. Clinical and Population Cytogenetics Unit, Western General Hospital, Crewe Road, Edinburgh EH4 2XU, by March 31, 1979. 9834(A).

SCIENCE, ENGINEERING AND TECHNOLOGY

The British Council

OVERSEAS CAREER SERVICE

The British Council, which has a responsibility for Britain's cultural and educational relations overseas, will have some vacancies in 1979. The Council is represented in over 80 countries. Overseas Career Service staff must expect to serve wherever they are posted, and to spend two-thirds or more of their working lives abroad.

Staff joining the Overseas Career Service bring with them a wide variety of skills and experience and most appointments are made with a view to eventual promotion on merit to senior managerial posts. The Council has a continuing need for a proportion of new staff with qualifications and experience in science and engineering, as well as in the other specialist subjects of interest to the Council: English language teaching and librarianship for example.

We should like to hear from you if you have a background in science or engineering and some postgraduate experience in research, industry, education or administration. An essential requirement is the personal and managerial qualities which overseas representation demands.

Recently, most successful candidates for the Overseas Career Service have been between 25 and 32 years of age, but we should be glad to hear from younger or older candidates who have the necessary background. Only in exceptional cases is appointment offered to candidates over the age of 40.

The initial salary is in the region of £5,300, possibly higher for particularly well-qualified candidates, and terms and conditions of service are in line with those of comparable organisations in the public sector: free accommodation and overseas allowances, including children's education allowances, are provided while overseas.

For further details and an application form, please write or telephone quoting C1 to Staff Recruitment Department, The British Council, 65, Davies Street, London W1Y 2AA, telephone 01-499 8011, extension 3041.

9878(A)

THE UNIVERSITY OF HULL CURATOR OF THE GEOLOGICAL COLLECTIONS

Applications are invited for the post of Curator in the Department of Geology, tenable from September 1, 1979. The person appointed will be responsible for curation of the Department's teaching and research collection of rocks, minerals, fossils, maps and pamphlet collection, and the work will include the design and execution of exhibits. An honours degree in geology is required.

Salary will be on the Other Related Staff Grade 1B scale: £3,384 to £4,882 (bar) (under review), initial placing depending on age and qualifications.

Applications giving details of age, qualifications and experience, together with the names of two referees, should be sent by April 30, 1979 to The Registrar, The University of Hull, Hull, HU6 7RX from whom further particulars may be obtained.

Bio-Organic Research Group

RESEARCH ASSISTANTS IN GENETICS, MICROBIOLOGY, BIO-CHEMISTRY AND CHEMISTRY (4 POSTS)

Applications are invited from graduates with an appropriate good Honours Degree to undertake research on the following projects:

Post 1 mutagenesis in antibiotic-producing *Streptomyces* (supported by Beecham Pharmaceuticals Ltd.)

Post 2 genetic studies of the yeast *Saccharomyces lipolytica* (supported by SRC)

Post 3 chemical identification of antibiotics produced by micro-organisms

Post 4 combined antibiotic and heavy metal resistance of bacteria found in freshwater and sewage

All assistantships are tenable for a maximum period of three years.

Successful candidates will be registered for a Ph.D. with the CNA.

Applications stating the project(s) of interest and including a curriculum vitae and names of two referees to Dr. G. Holt, Division of Science, PCL, 115 New Cavendish Street, London W1M 8JS. (Tel.: 01-486 5811, ext. 6367.)

9894(P)

UNIVERSITY OF CALGARY GRADUATE ASSISTANTSHIPS

(Teaching and Research)

Available for students proceeding to the M.Sc. and Ph.D. degrees in all branches of CHEMISTRY and BIO-CHEMISTRY. The assistantships are valued at \$7,000 to \$8,000 p.a. and include remission of program fees. Travel allowance also available.

For further information write to:

Department of Chemistry
Chairman of Graduate Studies
UNIVERSITY OF CALGARY
Calgary, Alberta, Canada
T2N 1N4

Please indicate field of interest.
9855(P)

UNIVERSITY COLLEGE LONDON

CHEMISTRY DEPARTMENT

Applications are invited for an S.R.C. Postdoctoral Assistantship to study ligand chemistry in transition metal clusters, in particular additions to aromatic bridging ligands and dnmr behaviour. The appointment will begin on October 1, 1979 for one year, with possible renewal for a second. Initial salary in range £3,909 to £4,158 plus £450 London Allowance. Applications with curriculum vitae and names of two referees, should be sent to Dr A. J. Deeming, Department of Chemistry, University College London, 20 Gordon Street, WC1H 0AJ.

9856(P)

UNIVERSITY OF OXFORD DYSON PERRINS LABORATORY POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a postdoctoral research assistantship supported by the S.R.C. to further develop and exploit a new method for measuring kinetic isotope effects (including those for 'heavy' atoms) with high accuracy. Preference will be given to candidates with experience in kinetics or in synthesis with stable isotopes.

The appointment is for two years, commencing October 1, 1979, or at an agreed date. The salary will be on the Research Support Grade Scale 1A, initially not higher than £4,130 p.a. (under review), plus U.S.S. benefits.

Applications (one copy), with curriculum vitae and the names and addresses of at least two referees (overseas applicants should ask referees to write directly to the address below) should be sent not later than March 31, 1979, to Dr M. J. T. Robinson, Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY, from whom further information may be obtained.

9801(P)

GRADUATE ASSISTANTSHIP leading to M.Sc. and Ph.D. in Chemical Engineering. Stipend up to \$7,200 p.a. tuition for qualified candidates. Active and stimulating research program. Write Dr. John A. Roth, Department of Chemical Engineering, Vanderbilt University, Nashville, Tennessee 37235. Equal Opportunity Employer.

9835(P)

UNIVERSITY OF CALGARY GRADUATE ASSISTANTSHIPS

(Teaching and Research)

Available for students proceeding to the M.Sc. and Ph.D. degrees in branches of CHEMISTRY and BIO-CHEMISTRY. The assistantships are valued at \$7,000 to \$8,000 p.a. and include remission of program fees. Travel allowance also available.

For further information write to:

Department of Chemistry
Chairman of Graduate Studies
UNIVERSITY OF CALGARY
Calgary, Alberta, Canada
T2N 1N4

Please indicate field of interest.
9377(P)

UNIVERSITY OF DURHAM DEPARTMENT OF APPLIED PHYSICS AND ELECTRONICS Applications are invited for an S.R.C. POSTDOCTORAL RESEARCH ASSISTANTSHIP

tenable for 3 years from May 1, 1979 or as soon as possible thereafter. Applicants should have qualifications in physics, materials science, electron or a related subject.

The successful applicant will be a team working on Electroluminescence in Zinc Sulphide in the group directed by Dr J. Woods, and will be concerned with the fabrication and evolution of light emitting diodes and larger area devices.

Initial salary on National Research Range 1A in the range £3,883 to £4,382 (under review), plus superannuation.

Applications (three copies) naming three referees, should be sent March 21, 1979, to the Registrar & Secretary, Science Laboratories, South Road, Durham DH1 1LE, from whom further particulars may be obtained.

9897(P)

FELLOWSHIPS

THE ROYAL SOCIETY
BRITISH GAS SENIOR
RESEARCH FELLOWSHIP

Applications are invited by the Council of the Royal Society for The Royal Society — British Gas Senior Research Fellowship for original scientific or technological research in a field of mathematics, chemistry, physics or engineering (including metallurgy and materials science, fluid mechanics, thermodynamics, combustion, heat transfer, biochemistry, and computer science) related to the production, transmission and use of natural gas and its substitutes.

Candidates, who must be citizens of the United Kingdom or the Commonwealth, should supply the usual personal details and two referees. Testimonials will not be considered. Candidates should state the subject of the proposed research and where it will be undertaken. It is expected that the successful candidate will spend a significant proportion of his or her time in direct collaboration with industry, evidence of existing contacts would be helpful. Applicants should obtain and give evidence of consent from the head of department or other authority in the university and/or industrial establishments in which the research will be done.

The appointment which will be subject to the Society's general regulations governing research appointments, will be tenable for five years from October 1, 1979 (or another date to be arranged), and may exceptionally be renewable for a further two years, such renewal being considered at the end of the fourth year of tenure. Applicants should preferably be under 45 on October 1, 1979. The present stipend scale is £8,031 by £252 to £8,787 by £249 to £9,036 per annum, and the point of entry will be determined by Council. Superannuation benefits will be provided. Some provision for research expenses will be available.

Applications should be made on forms to be obtained from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London, SW1Y 5AG, and should be received not later than March 31, 1979.

9819(E)

THE ROYAL SOCIETY
SENIOR RESEARCH
FELLOWSHIPS

Applications are invited by the Council of the Royal Society for up to three Royal Society Senior Research Fellowships for research in any scientific subject, established by funds from the Parliamentary Grant-in-aid. The appointments will be tenable in any appropriate university department or research institution in the United Kingdom approved by the Council of the Royal Society. Candidates, who must be citizens of the United Kingdom or the Commonwealth, must supply the usual personal details and give two referees. Testimonials will not be considered. The subject of the proposed research, and where it would be done, together with the name of the head of the department, whose consent should first be obtained, must be stated.

The appointments, which will be subject to the Society's general regulations governing research appointments, will be tenable for five years from October 1, 1979 (or another date to be arranged) and may be renewable for a further two years. Applicants should preferably be under 45 on October 1, 1979. The present stipend scale is £8,031 by £252 to £8,787 by £249 to £9,036 per annum, and the point of entry will be determined by Council. Superannuation benefits will be provided. Some provision for research expenses will be available.

Applications should be made on forms to be obtained from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London, SW1Y 5AG, and returned by March 1, 1979.

9820(E)

UNIVERSITY OF ESSEX
DEPARTMENT OF CHEMISTRY
POSTDOCTORAL
RESEARCH FELLOWSHIP

Applications are invited for a position as post-doctoral research assistant from October 1, 1979 to work with Dr. J. G. Tillet and Dr. R. M. G. Roberts in the field of organosulphur chemistry. This project is funded by the Science Research Council and will involve a kinetic study of the metal ion catalysed cleavage reactions of cyclic and open-chain disulphides. Appointment will be for two years and the salary will be on the Research Fellow 1A scale (plus superannuation).

Applications should reach the Chairman, Department of Chemistry, University of Essex, Colchester CO4 3SQ, from whom further particulars may be obtained by March 31, 1979.

9865(E)

UNIVERSITY OF
BRITISH COLUMBIA
Vancouver, B.C., Canada
POSTDOCTORAL
FELLOWSHIP

(two years) available immediately for research on the mechanisms of bacterial attachment to hard and soft tissue with emphasis on isolation and characterisation of cell surface components involved in bacterial attachment reactions.

Salary \$11,700 for first year and \$12,500 for second.

Send curriculum vitae and names of three referees to:

Dr B. C. McBride
University of British Columbia
Microbiology Department
2075 Westbrook Mall
Vancouver, B.C. V6T 1W5

9837(E)

THE ROYAL SOCIETY
THE BRITISH PETROLEUM
COMPANY LIMITED
SENIOR RESEARCH
FELLOWSHIP

Applications are invited by the Council of the Royal Society for The Royal Society — British Petroleum Company Limited Senior Research Fellowship, established by means of a five-year grant from the British Petroleum Company Limited for research in a subject field associated with the exploration, production and transport of fossil fuels and/or with the physical, chemical and mechanical properties of materials used in these operations. The Fellow will be expected to have an interest in the application of his research to practical problems. The appointment will be tenable in any appropriate university department or research institution in the United Kingdom approved by the Council of the Royal Society. Candidates, who must be citizens of the United Kingdom or the Commonwealth, must supply the usual personal details and give two referees. Testimonials will not be considered. The subject of the proposed research, and where it would be done, together with the name of the head of the department, whose consent should first be obtained, must be stated.

The appointment, which will be subject to the Society's general regulations governing research appointments, will be tenable for five years from October 1, 1979 (or another date to be arranged). Applicants should preferably be under 45 on October 1, 1979. The stipend scale will be £8,031 by £252 to £8,787 by £249 to £9,036 per annum, and the point of entry will be determined by Council. Superannuation benefits will be provided. Some provision for research expenses will be available.

Applications should be made on forms to be obtained from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London, SW1Y 5AG, and returned by March 31, 1979.

9818(E)

NEWCASTLE UPON TYNE
POLYTECHNIC
DEPARTMENT OF
ELECTRICAL ENGINEERING
AND PHYSICAL ELECTRONICS
FELLOWSHIP IN
PHOTOVOLTAIC SOLAR
ENERGY

The Fellow will collaborate with existing research groups in both a techno-economic study of the viability of photovoltaic power generation in a variety of economic and climatic conditions and in the development programme of sputtered thin film solar cells. Post tenable for five years, salary depending upon experience.

Burnham F.E.: Principal Lecturer
Scale: £7,047 to £8,844 per annum.

For further particulars and application form, returnable by March 15, 1979, please send a stamped addressed foolscap envelope to the Staffing Officer, Newcastle upon Tyne Polytechnic, Ellison Building, Ellison Place, Newcastle upon Tyne NE1 8ST.

9902(E)

UNIVERSITY OF
DUNDEE
POSTDOCTORAL
RESEARCH FELLOWSHIP
DEPARTMENT OF
CHEMISTRY

Applications from appropriately qualified candidates (either sex) are invited for a Postdoctoral Research Fellowship available for one year in the first instance but with the possibility of subsequent renewal for one further year.

The person appointed will work on an investigation of the photochemistry of some benzotriazine-3-N-oxides with Dr W. M. Horspool and Dr A. W. Murray (either of whom will be pleased to answer informal enquiries).

Initial salary £3,883 per annum (Research and Analogous Staff Range 1A, Point 1). Superannuation under U.S.S.

Applications, quoting Reference EST/29/79J and including a curriculum vitae and the names of two referees should be lodged with The Secretary, The University of Dundee, Dundee DD1 4HN by March 22, 1979.

9628(E)

STUDENTSIPS

THE ANIMAL VIRUS
RESEARCH INSTITUTE,
PIRBRIGHT
A.R.C. RESEARCH
STUDENTSHIP 1979

Applications are invited for an Agricultural Research Council Studentship to join a group working on the structure of foot-and-mouth disease virus RNA and the biochemistry of virus mutants as they relate to the function of the RNA. The Studentship will be tenable for up to 3 years from October 1979 and the successful candidate will be expected to read for a higher degree. Applicants should possess, or expect to obtain, a good honours degree in a Molecular Biological subject.

Application forms and further particulars may be obtained from the Secretary, The Animal Virus Research Institute, Pirbright, Woking, Surrey, GU24 0NF, applications should be received by March 31, 1979.

9845(F)

THE MEDICAL COLLEGE
OF ST. BARTHOLOMEW'S
HOSPITAL
(University of London)

Applications are invited from good honours graduates and those expecting to graduate in 1979 for

COURSES AND CONFERENCES

IId Announcement

IVth Colloquium :

HORMONES AND CELL REGULATION

(03/10/1979—3 p.m. to 06/10/1979—1 p.m.)

The 'Institut National de la Santé et de la Recherche Médicale' is organising its annual meeting on cellular regulation at the Bischoffsberg (near Strasbourg). The aim of the Conference is to present reviews of recent advances in general lectures and communications of hot unpublished results by posters, both being analysed in general discussions.

Organisers:

J. NUNEZ, H. DENTON, J. E. DUMONT, D. HEPP, B. JEANRENAUD, I. MCINTYRE, S. MOREL, G. SCHULTZ, H. J. VAN DER MOLEN.

Preliminary programme:

General lecture: J. P. EBEL (Strasbourg)

Cyclic Nucleotides: J. G. HARDMAN (Nashville), Z. SELINGER (Jerusalem), S. VAN HEININGEN (Edimburg), G. ROSSELIN (Paris)

Mechanisms not related to cyclic nucleotides: H. DEWULF (Leuven), R. H. MITCHELL (Birmingham), K. JACOBS (Heidelberg)

Insulin: P. DE MEYTS (Leuven), H. BLUNDELL (London)

Steroids: C. B. BOYD (Edimburg), GEHRING (Heidelberg), K. AHREN (Göteborg)

Opiates: B. HAMPRECHT (München), C. KORDON (Paris)

Differentiation: N. LE DOUARIN (Paris), R. KRAM (Brussels), L. HOUEBINE (Jouy en Josas).

Participants can present posters related to the topics of the Conference.

Afternoons are free with a wide-range of leisure activities (tennis, table-tennis, etc.).

The general attendance is limited to 100 persons.

Registration fee: 200 F.F. Room and board can be obtained at the site of the Conference. Provisional prices, 725 F.F. (double room), 900 F.F. (single room). A limited number of fellowships will be available to help young investigators who have a special interest in the program and who cannot otherwise attend the Symposium.

Investigators interested in attending the meeting and/or presenting a poster should submit an application form to the secretariat:

Dr J. NUNEZ—INSERM—Unité de Recherche sur la Glande Thyroïde
79, av. de Général Leclerc, 94 BICETRE—FRANCE

9740(C)

EMBO COURSE ON MEMBRANES & THE CYTOSKELETON

October 1-10, 1979

European Molecular Biology Laboratory Heidelberg, F.R.G.

The course will be organised by the Membrane Group at EMBL and will comprise a series of lectures (1-3 October) and practical work (4-10 October).

The teaching staff will include: M. Bretscher (U.K.), J. Goldstein (U.S.A.), W. Franke (F.R.G.), R. Henderson (U.K.), R. Kemler (France), J. Rothman (U.S.A.), G. Palade (U.S.A.), P. Peterson (Sweden), T. Pollard (U.S.A.), P. Robbins (U.S.A.), G. Schatz (Switzerland), W. Sebald (F.R.G.) and K. Weber (F.R.G.);

and the following staff members of EMBL: B. Dobberstein, H. Garoff, G. Griffiths, A. Helenius, B. M. Jockusch, D. Louvard, K. Simons, G. Warren and H. Weiss.

Practical work will include: Membrane reconstitution; biosynthesis of membrane proteins *in vitro*; immunofluorescent microscopy and electron microscopy of the cytoskeleton.

A maximum of 36 students will be able to attend. Applications should include a short curriculum vitae and a description of present research interests. For further details write to:

Graham Warren,
EMBL,
Postfach 10.2209,
D-6900 HEIDELBERG, F.R.G.

The closing date for applications is May 1, 1979. 9906(D)

THE NEW YORK ACADEMY OF SCIENCES

Conference on

REGULATORY FUNCTIONS OF INTERFERONS

New York City, October 23-26, 1979

The New York Academy of Sciences is planning to sponsor a four-day Conference on interdisciplinary aspects of interferon research. The Conference is co-chaired by J. Vilcek (New York University), I. Gresser (Institut de Recherches Scientifiques sur le Cancer, Villejuif) and T. C. Merigan (Stanford University). The Conference will cover: immunoregulatory actions of interferons; regulatory effects of interferons in lymphocytes, macrophages and other cells; interferons as lymphokines; cell growth inhibitory and antitumor actions of interferons; genetics of the interferon system; purification and properties of interferons; molecular mechanisms of interferon action.

To supplement invited lectures, the organising committee will accept suitable poster session presentations. The deadline for the submission of abstracts to be considered for poster presentation is June 1, 1979. The abstracts should include the name of the author(s), institution and 100-200 word summary of work to be presented in the poster. Send abstracts for poster session and inquiries about details of the program and registration to:

Conference Director,
New York Academy of Sciences,
2 East 63rd Street,
New York, NY 10021.

9757(C)

UNIVERSITY OF LONDON
KING'S COLLEGE

M.Sc.

in

HUMAN AND
APPLIED PHYSIOLOGY

A one-year course to train graduates in measuring and studying the physiological functioning of man in normal and abnormal environments. The course would equip students to specialise in the applications of physiology to man in industrial, service and clinical situations and the teaching of human physiology. Topics studied include:—basic measurements; life support systems; exercise; locomotor; postural; climatic; high altitude and hyperbaric physiology.

October 1, 1979 to September 30, 1980.

Applicants should have a good degree in Physiology or be medically qualified.

Further details and application form from: Dr S. Rowlands, King's College, Strand, LONDON WC2R 2LS, quoting reference N 1/3.

Closing date for applications: March 31, 1979. 9811(D)

UNIVERSITY OF BRISTOL
M.Sc. (MEAT SCIENCE)

This course occupies one calendar year and leads to the degree of M.Sc. (Meat Science) by examination and dissertation. Candidates should have either an honours degree in the biological sciences or a degree in veterinary science. Applicants with other qualifications, if combined with previous industrial research or experience, may also be considered.

The course provides a systematic programme of study at an advanced level covering the whole field of meat science. Instruction will be provided by the staffs of the University School of Veterinary Science and of the Agricultural Research Council Meat Research Institute, which are both situated on the University's estate at Langford, about 14 miles south of Bristol. Accommodation is available in halls of residence.

Starting with the production of meat animals, the course extends through the scientific bases of all the operations involved in the production of meat and meat products, and includes consideration of the economics of the industry and of its controlling legislation. The objectives of the course are to equip graduates to apply the principles of meat science within the industry, to operate effectively in posts with responsibility for its legislative control or to provide them with the foundation for a career in meat research.

For further particulars please apply to:

The Registrar and Secretary,
(Ref. CYF),
University of Bristol,
Senate House,
Bristol BS8 1TH.

POSTDOCTORAL
RESEARCH
ASSOCIATESHIPS

Applications are invited from
physical chemists and physicists for
the above posts to carry out two
S.R.C.-sponsored research projects
in collaboration with Professor
Graham Williams.

One post will be concerned with
research into the behaviour of
liquid-crystal-forming materials, at
temperatures a little above their
clearing points, as studied using
modern electro-optical techniques.
The second post will be concerned
with research into the molecular
interactions (including complex-
formation) of polymer systems, as
studied using modern electro-
optical and dielectric techniques.

The posts are for up to two years
from August 1, 1979. The starting
salary will be up to point 3 of the
Range 1A Scale (£3,883 to £4,382,
interim award).

Applications, enclosing a curri-
culum vitae and the names of two
referees should be submitted by
April 6, 1979 to Professor Graham
Williams, Edward Davies Chemical
Laboratories, University College of
Wales, Aberystwyth SY23 1NE.

LUMINESCENCE... What can a lifetime do for you?

PRA's pulsed nanosecond fluorometer systems now make the measurement of luminescence lifetimes routine procedure with highest result confidence.

Uses:

- Elucidate complex photophysical mechanisms
- Identify the presence of more than one fluorescent compound
- Open new ways of probing luminescent systems
- Can be highly sensitive to sample impurities
- Lamp can be used as pulsed light source
- Determine lifetimes as short as 200 picoseconds
- Less than 100 picoseconds time uncertainty

Features:

- High signal to noise ratio
- Low RF interference
- Low scattered light levels
- Complete computer interface and software options available

Competent consulting staff with broad experience in instrumentation and applications to advise you

The choice of the best.

It just had to be a Wild instrument. They're optically and mechanically tops, world wide. And if I want to use a special technique, there'll certainly be a suitable additional set of accessories. But what a range of stereomicroscopes! The Wild consultant soon showed me the differences between them. There's the **Wild M1A** for process and control work in industry; the **Wild M1B** for educational work; the **Wild M3**, with three-step magnification changer, for the laboratory. The **Wild M5A** has the greatest magnification

range — up to $250\times$ with its coaxial illuminator. And then come the zoom stereomicroscopes; the **Wild M7A** with stepless variation of magnification within the range 1:5; the **Wild M7S**, specially for photomicrography and polarisation; and the **Wild M8**, with 1:8 zoom range. And, if you want to photograph in the macro range, you'll certainly be enthralled by the **Wild M400 Photomakroskop**. But to examine highly-reflecting surfaces or thin layers, the **Wild M450 Epimakroskop** is the answer. Ask for brochure M1 180e.

Why is a beautiful
hotel like the Pulitzer
featured in a
magazine like this?

Guess!

Even a scientist needs to relax

The four star Pulitzer is located along one of Amsterdam's most famous canals in the heart of the city. 17 historic buildings were completely restored to their original beauty and combined to house 175 guest rooms all with modern facilities. Graced with beams and natural brick walls, each room reflects a rustic charm not found elsewhere in Amsterdam.

You'll find a cozy bar to relax after a busy day. A restaurant which serves delicious Dutch and French food. And keep in mind that the Pulitzer has private meeting facilities up to 60 persons.

So when you're planning a trip to Amsterdam, remember the Pulitzer.

A new approach in tissue culture

PETRIPERM

a novel culture dish
with gas permeable
membrane as cellular
support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents

PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.

In the intact animal, the pH, and the partial pressure of both oxygen and CO₂ of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO₂, pCO₂ and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 μm thick membrane.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely.

Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976).

applied excellence

Advanced techniques in routine use at The Radiochemical Centre

Described below are just two examples of the many up-to-date techniques, which have been pioneered or applied for routine use at The Radiochemical Centre. These developments are part of our constant endeavour to maintain our position at the forefront of the specialised field of tracer methodology, so that we can continue our supply of radiochemicals of the highest quality and technical specifications.

Distribution of labelling in tritium compounds

Modern techniques for the production of tritiated compounds are more sophisticated than those used in the early days of tritium labelling, and produce compounds labelled in specific positions rather than generally labelled. Nevertheless, it is necessary for many tracer applications of tritium compounds to know the *precise* position and configuration of the tritium labels. Traditional chemical methods of doing this are tedious and time consuming and subject to considerable error, and so the routine supply of such information has until recently not been possible.

The Radiochemical Centre, in collaboration with the University of Surrey, has developed over the past eight years the technique of tritium nuclear magnetic resonance (tnmr) spectroscopy for this purpose. This method is much quicker and more accurate than the traditional chemical or biochemical methods for determining distribution of tritium labelling.

It is now used routinely to establish the distribution of tritium labelling produced by the usual methods of tritiation employed at The Radiochemical Centre. We supply accurate details as to the position and configuration of the tritium labels for an increasing number of our labelled compounds.

A number of examples are given below:

	[18, 20(n)-³H]TESTOSTERONE Code TRK.162 1α 5.9% 2α 8.2% 1β 46.0% 2β 39.9% [6-³H]BENZO[a]PYRENE Code TRK.501 6 >95% 1 <5% D-[2-³H]GLUCOSE Code TRK.361 2(α) 40% 2(β) 60% L-[3,4(n)-³H]VALINE Code TRA.K.533 2 8% 4 64% 3 28%

Circle No. 08 on Reader Enquiry Card.

High performance liquid chromatography (HPLC)

This relatively new development of column chromatography is carried out using high efficiency microparticulate column packings of closely defined size.

Chromatography is carried out under pressure to ensure good flow rates and reduce diffusion of separated compounds. Dead volumes are kept to an absolute minimum. The result is that many separations can be carried out more quickly and with better resolution than with previously used chromatographic methods such as thin-layer chromatography or conventional column chromatography.

Work aimed at developing the applications of this method to radiolabelled compound separations is still in progress, but The Radiochemical Centre is already using the technique in many of its production processes, and in analytical applications. The result is purer compounds for the customer and greater efficiency of working.

The example illustrated below illustrates the clear superiority of HPLC when used as an analytical tool. The mixture used comprised the tritium labelled mono-, di- and triphosphates of adenosine, cytidine, guanosine and uridine, and all are clearly separated in the HPLC system.

Better information about development

WHEN the United Nations Conference on Science and Technology for Development (UNCSTD) comes to an end in Vienna in late August, what will it leave behind for the future? Many hope it will not spawn another UN agency or office, as there are enough of them already. But in individual countries there could be a valuable legacy: as a result of preparations for UNCSTD many nations have brought together a wide range of people—administrators, politicians, industrialists, trade unionists, academics—to discuss national problems, be they those of rich or poor countries. If these networks survive and continue to talk to each other then UNCSTD will not have been in vain.

Britain has kept such a low profile both domestically and internationally over the UNCSTD meeting that to talk about networks having emerged from any national debate on the subject would be entirely fatuous. And yet there is at present the possibility of raising public awareness about development questions.

The Overseas Development Ministry recently commissioned a survey on public attitudes towards overseas development and found a substantial decline in support for British aid since the last such survey (in 1969).

Whilst only a few per cent are against richer countries giving help to poorer countries, 39% of those interviewed were against Britain herself giving aid. And few were able to give even an order of magnitude estimate of how much the country spends on overseas aid, generally overestimating the figure. As interviews progressed and those interviewed were told Britain's actual expenditure, a significant shift in

attitudes occurred and support for more expenditure grew substantially.

Part of the reason for ignorance and distrust of overseas aid could simply be low public awareness of what is involved in an aid programme. Such a conclusion would be reinforced by comparative statistics on how much Britain spends on education about development: Britain's spending on education about overseas development has until recently amounted to about £215,000 per annum—about 0.3p per capita. This contrasts very unfavourably with countries such as Germany and Canada (spending 2p and 7p per capita respectively), and doesn't bear comparison at all with expenditure of 10p per capita in the Netherlands or 15p in Sweden. Now spending is going up enormously; a recent ODM working party on the subject recommended a budget of £2.7 millions for development education by 1982 (*Overseas Development Paper 14*, HMSO) and the government has accepted these proposals.

Universities should take advantage of this new scheme. By no means all ignorance of the problems of the developing world is confined to those who never benefited from higher education; indeed most students are unlikely to be made to think at all about these matters during their formal coursework except, perhaps, in a handful of lectures in an optional course on science and society. Better informed graduates in science and technology might make for more soundly-based judgements later in life. The financial means for providing better information are now available. Who will take them up? □

JET—an insoluble salary problem

READERS of the classified advertisement section of *Nature*—most of our readers tell us they turn to it first—will not be unaware of wide differentials in salary. If you work in a British university, or for the British civil service, the salary scale will be tightly defined to the fourth significant figure of a very modest sum. Find a post in a continental university and the salary doubles, at the least. The cost of living goes up too, of course, although few would deny that, taken all in all, the scientist in England is ill-paid in comparison with his continental colleagues.

It is the posts in international organisations which really raise the eyebrows, however. Many of these positions are either tax-free or subject to very modest taxes indeed. Recently, for instance, readers will have noticed such choice offerings as the directorship of an internationally sponsored laboratory in Monaco, no less, at £24,000 per annum, tax free. This is hardly an unusual sum; researchers with several years' experience can command the same at CERN.

What happens, however, when internationally sponsored laboratories, with their traditionally high tax-free salaries come to Britain where the natives are ill-paid? The answer is—real recruitment problems, as those working on the Joint European Torus (JET) programme are finding out in their early days at Culham.

At the professional level, roughly one-third of the em-

ployees at JET are British, the rest are from other participating nations; at the senior technician level Britain supplies about 50% of the staff. The United Kingdom Atomic Energy Authority pays the salaries of Britons at its own standard rates subject, of course, to British taxes. Euratom supports the rest, who pay only a very modest 'community tax'.

Were Euratom to pay at the same rate as it does in Brussels, say, the differential between British and non-British employees' pay would be grotesque, so a figure of 62% of the Brussels rate has been established. Italians, for instance, still find this sort of salary attractive, but the same cannot be said for Germans—so there are differential recruitment problems. And even so, the 62% figure means that the net salaries of non-British employees are between 1.5 and 2 times greater than those of British counterparts. It is generally accepted that a factor of 1.3 to 1.5 is adequate compensation for living in a foreign country; there is little doubt that higher figures are ultimately going to be bad for morale.

At present, even if there are recruitment problems, the high level of motivation of the staff makes the salary question less important. But JET is a long-haul project, and the salary issue will not go away unless something quite remarkable happens to Britain and the pound sterling. □

'Emergency' ban on 2,4,5-T herbicide in US

Clive Cookson reports from Washington on swift reaction to a study linking 2,4,5-T with an increase in miscarriages

THE US Environmental Protection Agency has taken emergency action to ban the use of the controversial herbicide 2,4,5-T, after receiving new evidence linking it to a high incidence of miscarriages in Oregon.

"Studies completed only days ago show a high miscarriage rate immediately following the spraying of 2,4,5-T in the forests around Alsea, Oregon," explained EPA deputy administrator Barbara Blum. "This alarming correlation comes at a time when seven million pounds of 2,4,5-T are about to be used to control weeds on power line rights-of-way and in pastures, and to manage forests across the nation".

These uses will be stopped immediately by "emergency suspension"—the most drastic action EPA can take against a herbicide or pesticide, and the first time it has ever been invoked. The closely related herbicide, Silvex, which is used primarily to kill weeds on suburban lawns, is also covered by the order. But the remaining legal uses of 2,4,5-T, on open ranges and rice fields, are not included and may continue, the EPA said, "because they appear at this time not to involve human exposure comparable to the suspended uses".

However, the Environmental Defense Fund has rejected this argument and petitioned EPA for a total ban on all uses.

2,4,5-T [2,4,5-trichlorophenoxyacetic acid] and Silvex [2-(2,4,5-trichlorophenoxy)propionic acid] are both contaminated with small amounts of 'dioxin' (TCDD), which produces birth defects, miscarriages and tumours in animals, even at extremely low concentrations. The dioxin is thought to be responsible for their ill effects on animals.

For eight years, US environmentalists have been fighting legal and administrative battles against the continued use of 2,4,5-T (which was applied as a military defoliant in Vietnam and was widely blamed for the high incidence of birth defects there). But the EPA claims that its latest study is the first to link the herbicide clearly to ill effect on humans.

The agency commissioned the study last year when nine women from Alsea wrote to say they had had miscarriages after the national forest there was sprayed with 2,4,5-T. Scientists from Colorado State University and the University of Miami medical school compared miscarriages in the Alsea basin (western Oregon) with a control

population in rural eastern Oregon. They reported that:

- The miscarriage rate in the Alsea area was significantly higher than in the control area, where 2,4,5-T was not sprayed.
- The rate peaked dramatically in June in each of the six years studied, two or three months after the annual spring spraying. The spontaneous abortion index in June over the period 1972-77 was 130 per 1,000 births in Alsea and 46 per 1,000 in the control area.

Dr Blum said: "It's a remarkable correlation. While it is not proof of a cause and effect relationship, it is highly suggestive, particularly in light of animal data, and gives great cause for concern". She estimated that four million people across the United States would be protected by the emergency action.

The EPA claims that the short-term economic impact of the ban will be slight, because alternative herbicides are available for use on pasture and rights-of-way, and only 0.2% of the country's commercial forest area is sprayed annually. The long-term cost to forestry of a permanent ban could be \$7m-12m a year, because other herbicides are less effective and more expensive.

Dow Chemical is the leading manufacturer of 2,4,5-T and Silvex. A few

Dioxin: the 10-year battle that began with Agent Orange

Alastair Hay traces the steps leading up to the EPA ban

EVER since the late 1960s when the herbicide 2,4,5-T was found to contain the extremely toxic contaminant 2,3,7,8-tetrachlorodibenzodioxin (dioxin), there has been much concern over its continued use. It has already been banned in some European countries.

According to Mr Frank Parsons of the EPA's Pesticide Programme, 2,4,5-T is the biggest single issue the agency has had to deal with so far. In April last year, the agency issued its "Rebuttable Presumption against Registration and continued Registration of Pesticide Products containing 2,4,5-T", and interested parties were given 45 days in which to submit evidence supporting or opposing the use. An additional 60 days grace was granted following a request from one

of the major manufacturers for more time to present its case.

Parsons says that the EPA has received over 2,700 submissions on 2,4,5-T ranging from a 2,300-page memorandum from Dow Chemical—the major manufacturer of 2,4,5-T—supporting its use, to individuals claiming they were sprayed with the herbicide and their "hair dropped out". Asked how seriously the agency considered such comments, Parsons said that if enough of these claims are made "we can't ignore them." But the main protagonists in the debate are the chemical manufacturers and environmental pressure groups.

During the Vietnam war, Dow supplied most of the 2,4,5-T used by US forces in their defoliation programmes in Vietnam. It was used at that time in a 1:1 combination with 2,4 dichlorophenoxyacetic acid, called Agent Orange.

In 1969, Agent Orange was reported to be teratogenic (causing foetal abnormalities) in a study published by the US Bionetics Research Laboratory. Although it was subsequently shown that it was the dioxin con-

taminant—sometimes present in quantities in excess of 30 ppm—which was teratogenic and not 2,4,5-T itself, the Bionetics study led the US Government to withdraw Agent Orange from Vietnam and to restrict 2,4,5-T use in the US to forestry and clearing rights of way.

It was the high dioxin contamination which marked 2,4,5-T as a teratogen. The EPA reasoned, therefore, that reducing this contamination to less than 0.1 ppm might render it safe. However, as more evidence about dioxin's toxicity accrued, the agency was forced to review the situation. In 1972, Dow obtained a temporary court injunction preventing EPA from taking further action against 2,4,5-T. The following year, this was overturned by the US Court of Appeal. When the first hearings were held by the EPA in 1974 they proved inconclusive: there was insufficient data supporting allegations that dioxin in 2,4,5-T presented a health risk, and an order proposing the cancellation of 2,4,5-T was withdrawn.

The latest evaluation of the herbicide has thus been a continuation of

other firms also make them. Although the emergency suspension took effect from the moment it was announced on 1 March, the companies can appeal to have it lifted. When the suspension issue is settled, "cancellation hearings" will begin, to determine whether the herbicides should be banned permanently. That will take years to decide. □

EPA disputes Dow claim

The Environment Protection Agency has disputed claims by Dow Chemical that some dioxin compounds found in the environment are the result of normal combustion processes. The claim was made by the chemical company last November as part of its defence against charges that pollution associated with its herbicide production plant at Midland in Michigan was resulting in trace elements in fish in the Tittabawassee River.

Dow claimed that, since it had found dioxins associated with a number of combustion sources including car exhaust and charcoal grills, dioxins were formed by normal combustion processes. But EPA says this claim was based on purely circumstantial evidence. It points out that evidence submitted by Dow to the EPA shows dioxin levels two to four times higher in Midland than in other locations checked. It also criticises Dow for using analytical techniques and procedures which have not yet been corroborated by other scientists. □

Dow admits 'poor' lab results

THE US Environmental Protection Agency (EPA) has not only been reviewing the safety of the herbicide 2,4,5-T; it is also engaged in a major collaborative programme with US scientists to compare laboratory measurements of 2,3,7,8-tetrachlorodibenzodioxin (dioxin) — a toxic contaminant present in the herbicide.

Central to the EPA's concern about dioxin is the poor reproducibility of dioxin measurements. In an attempt to find out which laboratories were reliable the EPA induced five labs to take part in a collaborative programme. The results of this collaboration were reviewed at a recent meeting in Washington organised by the agency.

The potential threat posed by 2,4,5-T is that its dioxin contaminant will enter the human food chain. US scientists claimed recently that dioxin had been detected in beef fat and human milk. The same two vehicles were therefore chosen by the EPA for its programme. Fat and milk samples were 'spiked' with dioxin in quantities ranging from 0–8 ppt (parts in 10^{12}) and extracts prepared suitable for analysis. The extracted samples, together with known standards—all prepared by the EPA Pesticide Monitoring Laboratory at Bay St Louis, Mississippi—were randomised and sent to the five participants: the Dow Chemical Company; Harvard University; the University of

Nebraska; Wright State University, Ohio; and the EPA Health Effects Research Laboratory (HERL) in North Carolina.

If proof were needed that there is inter-laboratory variation, then this study provided it. Only two laboratories performed well in the study—those of Dr Michael Gross of Nebraska and Dr Matthew Meselson of Harvard. The EPA's own laboratory results were regarded as reasonable by scientists present at the meeting but those of the other two were felt to be poor—Dow's being the less accurate.

The fact that Dow Chemical performed badly in this collaborative programme has not passed unnoticed by some scientists in the field. They argue that it should have been Dow, a company with a long-standing interest in dioxin measurements, which came out at the top of this league table. Dr Warren Crummett, of Dow, confessed that his results were "poor". "They were worse than normal", he told *Nature*. According to Crummett, some of the blame lies with the method of dioxin extraction chosen by the EPA. Had Dow done its own extracting procedure, then, Crummett was convinced, his laboratory's results would have been much better.

Of the five laboratories, only Gross's performed well in identifying 'false positives' and 'false negatives'. Discon-

the earlier reviews, but with the difference that all sides have been claiming sufficient evidence to support their case. Mr Gary Jones, a spokesman for Dow Chemical told *Nature* in an interview before the EPA ban was announced that the company's view was that "if, with all the confidence we have on the safety of 2,4,5-T, we can't say it is safe, then we can't prove the safety of aspirin".

The company felt that the attack on 2,4,5-T is part of a campaign by environmental groups whose campaign will not stop with the banning of the herbicide. Dow sees itself as defending an attack on the chemical industry by environmentalists who, Jones said, "want to go back to windmills". Jones added that Dow was defending 2,4,5-T not because the herbicide is a large revenue earner—sales worth \$12m represent only about 0.2% of the company's total annual income—but because it is "science which should be determining 2,4,5-T safety, not emotion".

The basis of Dow's argument is that dioxin at 0.1 ppm in 2,4,5-T presents no human health hazard. The company has been defending this

claim not only before the EPA but also in a New York federal court. Dow and five other US manufacturers of 2,4,5-T are being sued for \$10m by the estate of a 28-year-old Vietnam veteran, Paul Reutershan, who died in December last year of terminal cancer of the colon.

Reutershan, a helicopter crew chief in the Vietnam war, flew on several herbicide spraying missions during which Agent Orange was used. Ten years later when he was diagnosed as having cancer, Reutershan was convinced that dioxin was the cause. Following his death, a new suit was brought on his behalf as well as on that of "all American servicemen whose health has been damaged, or is likely to be damaged, because of contact with Agent Orange". The new suit has been filed by a veteran attorney of chemical contamination cases, Victor Yannacome Jr, and is likely to prove a test case.

There is little comfort for the litigants, however, from the Veterans Administration (VA). The VA has reviewed some 500 claims from ex-servicemen—mainly from the Chicago area—that exposure to 2,4,5-T has

damaged their health. But, a spokesman said, the administration has not been able to prove that "any of these claims are herbicide-related".

Environmental groups such as the Environmental Defense Fund insist that the very presence of dioxin renders the use of 2,4,5-T dangerous. For these groups the fact that dioxin has been shown in three separate studies to be a carcinogen, and that it is always present as a contaminant in 2,4,5-T—albeit at a low concentration—is sufficient to proscribe its use in any circumstances.

Balancing these conflicting arguments was apparently a difficult exercise for the EPA. Before the ban was announced, the Agency admitted that it was practically impossible to do a "precise reckoning" of the risks and benefits of the herbicide. One official of the Agency confessed that the "political climate is terrific on this issue" and that it did complicate matters. However, as he saw it, the EPA's role was to review the evidence and if the Agency made both the environmentalists and industry unhappy then "we are probably doing our job".

certainly the other four all failed to single out enough of these 'false' values. There was some agreement among those present at the Washington meeting that dioxin values close to the detection limit—regarded as being 9 ppt—did complicate matters and that perhaps some false positives and negatives were unavoidable.

In future, the researchers will probably abide by the gentleman's agreement practised so far that only values which are at least 2½ times greater than the noise levels will be regarded as true measurements. This decision could well eliminate some of the false predictions. Some scientists—notably those at Dow—feel that dioxin estimations lower than 9 ppt must, therefore, still be treated with scepticism. Others still disagree, and argue that it depends on the methods of estimation.

Contamination of the dioxin extracts by other chlorinated hydrocarbons—PCBs, for example—makes interpre-

tation more difficult. Dow argue that this could be one reason for their poor results and that their extraction would produce a "cleaner" sample. However, contamination is not the only problem. There is still no measure of agreement between the practitioners on the methods to be used to estimate the recovery of the final dioxin sample.

Dioxin chlorinated with ³⁷Cl is used in most cases for this purpose: the tracer is normally incubated with samples before extraction, but there are still doubts in the minds of some of the researchers that this tracer 'equilibrates' with the natural dioxin to a sufficient extent so that estimates of the final recovery are indeed accurate.

There are doubts too about mass spectrometry readings and views differ as to whether two dioxin ions with a selected mass from natural dioxin (320 m/e, 322 m/e) should be measured and the results averaged or whether one mass reading is sufficient. The

results in the EPA review are more or less independent of the method of measurement—good and poor results were recorded by both mass spectrometry methods.

Although some of these views have still to be resolved there was still general agreement at the meeting that the EPA should publish the results of this collaborative programme as soon as possible and that it should be subject to peer review. However, whether the reviewers agree with the consensus of opinion expressed at the meeting that dioxin analysis has become far better in the past few years remains to be seen.

What they will undoubtedly say is that there ought to be even more collaboration between laboratories to ensure greater reproducibility of results. As for the EPA, it will probably be given credit for initiating the first major stage in this collaboration.

Alastair Hay

Chemicals in food: new US framework proposed

A NEW framework for regulating toxic substances in food, which would give greater discriminatory power to the Food and Drug Administration, and allow the benefits as well as the risks of a particular substance to be taken into account, has been suggested by a study group of the National Academy of Sciences.

The proposal is made in a report published last Friday by the Academy's Institute of Medicine and National Research Council, prepared at the request of Congress following the controversy two years ago over whether or not saccharin is carcinogenic, and if so what should be done about it.

According to the panel of scientists, lawyers and public policy experts which prepared the report, the proposed framework—under which a substance could be placed in a category of high, moderate or low risk, with discrimination given to the FDA over handling substances in each category—would effectively separate the scientific assessment of risk from its social consequence.

In a letter submitting the report to Health Secretary Mr Joseph Califano, for example, Dr Philip Handler, president of the academy, says: "estimation of risk is a scientific matter, albeit not always readily feasible. Decision concerning the acceptability and management of a given risk is an intrinsically political question to be returned to the polity for determination."

Not all of the panel, however, agreed that the distinction is a tenable one. A minority report, disputing the suggestion that toxic food substances can

be divided into three categories according to varying degrees of risk, says that there is "no scientifically defensible way" of doing this.

The statement, signed by five of the 37 members of the committees responsible for the report, says that "the ability of science to quantify human risk has not advanced sufficiently since the formulation of the Delaney Amendment [which banned all food additives shown to cause cancer in laboratory animals] to permit the construction of a scientific rationale for such a scheme."

The report forms half of a two-part study carried out by the NAS under the terms of an act passed by Congress in 1977, which placed an 18-month moratorium on a ban on saccharin following the disclosure that it had been found carcinogenic in laboratory animals. The first part of the report was published last November, and concluded that saccharin was indeed a potential human carcinogen, although its potency was probably low compared to other known cancer-causing agents, such as cigarettes.

The second report is concerned with the public policy implications of this and similar findings for the regulation of food safety. It recommends a single policy applicable to all foodstuffs, additives and contaminants, and says that regulatory agencies should be able to do more than simply ban or not ban a particular substance.

"This report suggests that a realistic policy would be to weigh the estimated level of risk of a substance in our food supply against the perceived benefits of its use, and to employ informed

judgment as a basis for regulatory decisions," according to Dr David A. Hamburg, president of the Institute of Medicine.

A major problem presented by current law, the report says, is that most cases of both health and non-health benefits are excluded from regulatory consideration. "It is better to have benefits defined, evaluated and openly considered when that is possible", it says.

Speaking in Washington last week Professor Don K. Price, one of the panel members responsible for the report, denied that by shifting the focus of decision-making from Congress to a regulatory agency, the process would become more vulnerable to outside pressures. "The committee felt that the present scheme, which in theory asks the FDA to make a purely scientific decision, has not worked very well, and in many cases political and other considerations have been smuggled in—or, as in the saccharin case, have given rise to other problems", he said.

"This new system would require regulatory agencies to get a statement on the scientific aspects from a research institution, and the subsequent decision-making process can then be made clear, public and open, so that you can deal with it better than if you ignored outside pressure".

The committee made no particular recommendation for the marketing of saccharin, and the minority statement disagreed with the view of the majority that "a total immediate ban of saccharin would not be a sound regulatory step at the present time."

David Dickson

2,000 US scientists boycott USSR

IN what one participant called a "grass-roots" protest at the treatment of dissidents by the Soviet authorities, over 1,800 US scientists have signed a pledge to "withhold all personal co-operation with the Soviet Union" until Yuri Orlov and Anatoly Shcharansky, the two USSR scientists gaoled last summer, are released.

A further 600 US scientists have signed a separate pledge that they will not attend international conferences in the Soviet Union, will collaborate with and attend lectures by Soviet visitors only if they are invited, will oppose any enlargement of scientific and technical exchange programmes between the USSR and the US, and will "campaign against the transfer of sophisticated Western technology to the Soviet Union".

Signatures on the two petitions have been gathered by the Berkeley-based organisation Scientists for Orlov and Shcharansky, set up last summer when the trials of the two dissidents was taking place. SOS, as the organisation is known, says that its policy is to take concrete actions that deprive the USSR of some of the benefits of American science and technology, particularly in areas such as computing where the US has a considerable lead.

"The actions taken by SOS are a completely spontaneous response to Soviet policy, and are not connected to any position or policy of the US Government," Professor Kurt Gottfried, professor of physics at Cornell University, said last week.

"Our opposition to Soviet oppression is a limited response to Soviet actions, not a search for confrontation. Despite our commitment to human rights we view any linkage between human rights and the effort to achieve arms control as irresponsible," Professor Gottfried said, adding that SOS fully supported President Carter's efforts to negotiate a second Strategic Arms Limitation Treaty.

Gottfried was echoing Sakharov, who recently declared that human rights should not be made a *sine qua non* of the signing of the SALT agreement. While supporting Sakharov's opinion, John Macdonald, Q.C., Yuri Orlov's London-based "defence lawyer" nevertheless feels that the signing of SALT could lead to the release of political prisoners such as Orlov and Shcharanskii. It could well provide an opportunity for President Carter to press home the human rights issue—and for Mr Brezhnev to make a gesture which the Soviet Union could afford.

David Dickson and Vera Rich

Yugoslavia hits nuclear snag

PROPOSALS to build Yugoslavia's second nuclear power station on the island of Vir (see map) are meeting with opposition from the island's inhabitants, as well as the municipal authorities and 'socio-political organisations' of the nearby resort town of Zadar on the central Adriatic coast.

The local inhabitants and authorities seem more interested in preserving their amenities as a tourist area than in the alleged advantages which the plant would bring to the area—which is notably short in energy.

The vigorous opposition to the nuclear power station comes only a few weeks after a series of major power cuts so severe that even long-standing atheists were observed buying votive candles from church-porch stalls. Yugoslavia's major power source is hydroelectricity, and the dry autumn and early winter led in December to cuts of up to eight hours a day.

It was just such a drought, six years ago, that led to a big drive for alternative sources of energy. Five foreign enterprises competed for the contract for the first Yugoslav power station. Westinghouse won, and work began at Krsko, near the Slovenia-Croatia border.

The target date for completion was January 1979, but construction was consistently behind schedule.

The delays, however, did not relegate

nuclear power in the minds of the Yugoslav planners. By April 1978, the power industry was talking in terms of 12 nuclear power stations with a total annual capacity of 66,000,000 MWh by the end of the century.

So far, however, the Krsko station is still not operational and the siting of the second is in doubt. The final decision on the Vir site has not yet been reached—but local opposition suggests that a better choice might be Ivanicgrad, which not only has the necessary water resources, but is also a major industrial centre, where the local population may be less likely to raise environmental issues.

Vera Rich

UK must support talent, says minister

MRS SHIRLEY WILLIAMS, UK secretary of State for Education and Science, is concerned that not enough young scientists are finding jobs—because most available posts are filled by people in their thirties and forties who are unlikely to move on. "If science in Britain isn't to sink gently into the second class", she told the Association of British Science Writers earlier this week, "then we will have to try to make room for each generation of outstanding talent."

Making more money available to the research councils should help solve the problem, she said, and that was one of the reasons behind the 4% increase in the science budget announced at the end of last year. Another reason for increasing the science vote was to take the pressure off the SRC, whose budget had been "blocked up by existing commitments" and to encourage the funding of interesting or important work by the other research councils.

A white paper is to be published this week, said Mrs. Williams, about the 'customer-contractor' principle whereby a portion of research council funds is administered by ministries, which

commission research relevant to their needs. For the system to work, says Mrs Williams, "commissioned research has to be handled on a basis of stability and on a relatively long lead time". Problems occur if the level of research commissioned by a ministry is suddenly changed.

There is also a limit to that level and, according to Mrs Williams, the Agricultural Research Council's budget has already reached it. The increase in the science vote, however, should relieve some of the research council's dependence on commissioned research.

Mrs Williams is also concerned that the UK does not make the most of its innovative ideas. "It is sad", she says, "that one so often sees the brilliant idea worked on in a university laboratory being patented in another country and then sold back to us." She would like to see small companies encouraged to take up new ideas and the establishment of a "small enterprise board" which would assume for enterprise a similar role to that taken by the National Research Development Corporation for technology.

Judy Redfearn

news in brief

Reductions urged in medical radiation exposures: The elimination of all unnecessary medical and dental exposure to radiation was "critically important" to protect the health of the public, US Secretary for Health, Education and Welfare, Mr Joseph A. Califano, said last week.

Exposures resulting from X-rays, radiation therapy and nuclear medicine accounted for almost 90% of all the man-made radiation to which the general population was exposed, Mr Califano said, adding that he had ordered efforts by the DHEW through the Food and Drug Administration to reduce such exposures to be speeded up.

Commenting on Mr Califano's order, Dr John C. Villforth, director of the US Government's Bureau of Radiological Health, said that medical radiation should be cut to half of present levels.

"Approximately 30% of all medical exposures are unnecessary," said Dr Villforth, adding that many were done for non-medical reasons, such as protecting doctors from malpractice suits. The radiation dosage used in "necessary" medical procedures could be cut by another 30%, using the most recent X-ray films and machines.

However Mr Califano said that the US government was not yet prepared to recommend a reduction in permissible occupational exposure levels which has recently been suggested by a number of US scientists following growing evidence of the potential dangers of low levels of radiation previously treated as safe.

"We do not believe that the science is adequate to justify further reductions" he said, although stressing that more scientific research was needed to settle the issue, and that the problem was a "major public health issue."

Mr Califano released draft working papers which have been prepared by an Interagency Task Force on the Health Effects of Ionising Radiation, set up by President Carter last year. Reviewing past and current research, the task force states that "existing knowledge is insufficient to provide an unequivocal answer to the low-dose question", and adds that a definitive answer may never be found.

"I see Peterson's having his influence!"

Head of OTA resigns to head wildlife society: Mr Russell Peterson, former governor of Delaware, has resigned as director of the US Congress' Office of Technology Assessment to become president of the National Audubon Society. Mr Peterson's departure after only 13 months of a six-year appointment is a major blow to an agency which has been plagued with political problems. Under his leadership it had appeared to be entering a period of relative stability and productive activity.

Nuclear safety issue heats up: For ten years Dr Stephen Hanauer, assistant director and senior technical safety official of the US Nuclear Regulatory Commission has kept a 'nugget' file on reactor safety incidents. The Union of Concerned Scientists obtained a copy of the file under the Freedom of Information Act and has published a 95-page summary. Among its contents are tales of safety parts installed upside down, thickly painted and varnished rods or pumps sticking, frozen pipes, clogged drains, faulty

soldering, radioactive cleaning dust, accidentally bumped switches causing overflows and a \$45m fire that firefighters were afraid to put out because of the danger of spreading plutonium throughout the area. The US Atomic Energy Commission commented that "the absence of more serious effects is largely the result of luck".

In the UK, Friends of the Earth is pressing the Secretary of State for Energy to fulfill his promise to release the complete report of the Health and Safety Executive on the safety of pressurised water reactors. Only a summary was released on 29 July 1977. FOE cites the scandal surrounding the Rasmussen Report in the US which was issued in summary form and has been subsequently found so unreliable that the Nuclear Regulatory Commission dissociated itself from it. The Rasmussen summary included predictions that an accident at the Enrico Fermi reactor on 6 October, 1966, when part of a core fused, should have happened only once in a million years, and the same techniques predicted that the accident on 5 June 1970 when the 600 megawatt Dresden 2 reactor near Chicago went out of control and discharged radioactive iodine into the environment should have occurred only once in 10^{14} years. FOE stresses that "there is a clear cut need for public access to the Health and Safety Executive's detailed reactor studies".

INFCE halfway through: The International Nuclear Fuel Cycle Evaluation Programme established at the Western nations summit meeting in London in 1977 to study the hazard of nuclear proliferation is now halfway through its life with a report to be issued "sometime in 1980". INFCE began with some acrimony between the US and the UK over the danger of proliferation from nuclear reprocessing. The UK government is committed to reprocessing while American opinion is opposed to it. This difference in outlook colours the discussions of the twelve working parties. The US tries to win support for an extensive system of intermediate spent fuel storage deposits while the UK argues that such a system will be unnecessary if there is extensive reprocessing. Other preliminary studies indicate that there is no preferred "proliferation resistant" design: all proposed nuclear fuel cycles are equally hazardous. Factors included in the analyses are: extent of reprocessing, number of plutonium storage sites, and physical organisation of the fuel cycle (where fuel is to be stored in relation to the reactor), how buildings are to be laid out and the number of people to be involved. These "technical" issues are proving to be relatively unimportant compared to the political problem of proliferation.

Wave power cost estimates cut: Wave power designers at Wavepower Ltd in Southampton have found improvements in the design and manufacture of the Cockerell raft (30 November 1978, page 433) that may reduce projected costs from 26p per kwh to 6p per kwh. The original Cockerell raft was built in three sections with two hinges. The centre section contained a costly and complex pumping system and gearing train needed to drive the turbine. A new single hinge design eliminates the centre section and replaces the pumping system with a simple large-vaned pump that will be part of the raft structure. A more sophisticated but standard turbine will be used to effect power take-off. "We have thrown away a lot of steel and mechanical engineering" says Jim Platts, Senior Project Engineer at Wavepower. The new design will cut costs from 26p to 12p per kwh and a further reduction to 6p can be achieved by mass production methods based on techniques used in oil pipeline manufacture. Additional savings must be found, however,

Let us stop regulating DNA research

By J. D. Watson

The Royal Society critique (*Nature*, 15 February 1979, page 510) of the proposed new approach by Britain's Genetic Manipulation Advisory Group (*Nature*, 9 November 1978, page 102) to recombinant DNA regulation is correct on at least one point. We do not have the facts on hand to make the quantitative risk assessments to decide whether a proposed experiment should be done under maximal, minimal, or no precautions.

Assigning numbers in the manner suggested by Dr Sydney Brenner implies that we have some real measure of prospective risk. However, to my knowledge there is no evidence that any prospective recombinant DNA experiment poses any realistic threat to any scientist who uses the tools of his trade, much less to society itself. I thus do not see any logical way to arrive at such numerical risks, and the whole GMAG exercise strikes me as having no more validity than quantitative religion.

To be sure some experiments like putting *E. coli* genes back into *E. coli* are thought safe by virtually all informed individuals. In contrast, the insertion of the gene for the botulinus toxin into *E. coli* might strike some competent scientists as risky. But how much additional peril will be generated beyond that involved with working with botulinus organism itself is not obvious.

The *a priori* guesses that different knowledgeable minds will give may at best tell us something about their respective neuroses or lack of them. Each of us has different thresholds of fear, be it rational or irrational. For my part, I already see so many unambiguous hazards, like dioxin, that I remain incapable of adding still one more unless I see some real numbers. Recombinant-DNA-induced diseases to me fall in the category of UFOs or witches. Others may take

them seriously, but they should not expect me to join in. I would not spend a penny trying to see if they exist and would regard as pure folly the decision to spend sizable sums of money on such projects.

I am thus appalled by the recent proposals of the Honourable Joseph Califano and Shirley Williams that their respective governmental departments (HEW and the Department of Education and Science) initiate extensive experiments to probe the presumptive safety of recombinant DNA experiments. The variety of prospective experiments is so legion that we have no possibility of checking even a tiny fraction for their potential danger.

'Recombinant-DNA-induced diseases, to me, fall in the category of UFOs or witches'

Moreover, the answers we could obtain would have no real carry-over to other even closely related situations. So we would be spending vast sums of money (Shirley Williams has proposed tens of million pounds) merely to give the facade of responsibility. In fact, we would be irresponsible by diverting money away from projects which unambiguously might advance science, if not society itself.

We must thus be careful not to undertake risk assessment experiments merely because they can be done. Here I part company with the Royal Society's position that we should see, for example, whether non-pathogenic strains of *E. coli* can be converted into pathogens through random insertion of foreign DNA. Such data are very unlikely to affect the way we work with recombinant DNA. Unless we directly take DNA

from pathogenic bacteria, the chances of a positive answer are low. But even if we were to generate a new pathogen, it is not obvious that it would pose any special risk.

Almost totally lacking in the past six years of seemingly never-ending conjectures about the dangers from recombinant DNA experimentation is recognition of the fact that the world is already filled with large varieties of pathogenic microorganisms of many types. Moreover, they are constantly mutating to give us new forms that we have not seen before. Some are constantly making us ill, and sometimes even doing us in. For the most part, however, we can fight them at least to a draw, and, of necessity, most of us do not spend much time worrying whether the next time they will get us. Otherwise we would be completely paralysed from any constructive behaviour.

Instead of continuing to waste masses of paper and the time of countless individuals who have real jobs to carry out, I believe we should quickly and resolutely abandon any form of recombinant DNA regulation. Concurrently our national leaders should announce that they will help push DNA research as fast as our national and corporate treasuries can permit.

At the same time we should, of course, remain alert to the rare possibility that one or more recombinant DNA research workers will come down with a disease we have not seen before. If that happens we naturally would have a story that deserves serious journalism, and for the first time there would be real facts for the risk assessor. But until that situation arises, and I'm doubtful that it ever will, we must make clear to the public that there is no more reason to fear recombinant DNA than there is to panic about the Loch Ness Monster. □

if wave power is to be competitive with the estimated 1p-2p per kwh cost of windpower and with the standard fossil fuel costs of 1½p per kwh.

American Institute of Physics wins tax exemption: The American Institute of Physics, the umbrella organisation for nine separate physics societies, has won its appeal against a tax ruling that would have deprived it of tax exempt status.

Many of the institute's activities, including the publication of a number of journals, had been placed in jeopardy by a decision taken last year by the Manhattan District Office of the Internal Revenue Service that it was not entitled to

tax exemption as a scientific, educational and charitable organisation.

The institute filed a protest in December against this ruling, which is thought to have been made on the grounds that the institution provides a specialist service to its member societies which is not available to the general public.

In a letter received by the institute last week, the national office of the IRS said that it had considered the institute's appeal, and had decided in its favour. "The entire physics community will be pleased with the Internal Revenue Service ruling", said Professor Philip Morse, chairman of the AIP's governing board.

'Fortunately for us, plants are very adaptable and exist in great diversity . . . they could thus continue indefinitely to supply us with renewable quantities of food, fibre, fuel and chemicals'

Professor D. O. Hall of King's College, London University, on biological solar energy conversion for fuels

BIOLOGICAL solar energy conversion via the process of photosynthesis produces every year stored energy in the form of biomass which is about ten times the world's annual use of energy. The amount of proven fossil fuel reserves below the earth is only equal to the present standing biomass (mostly trees) on the earth's surface while the total fossil fuel resources are probably only ten times this amount (Table 1). This massive-scale capture of solar energy and conversion into a stored product occurs with only a low overall efficiency of about 0.1% on a world-wide basis but because of the adaptability of plants it takes place and can be used over most of the earth.

It is not widely appreciated that one-sixth of the world's annual fuel supplies are wood fuel and that about half of all the trees cut down are used for cooking and heating. In the non-OPEC developing countries, which contain over 40% of the world's population, non-commercial fuel often comprises up to 90% of their total energy use. This non-commercial fuel includes wood, dung and agricultural waste and because of its nature is seldom thoroughly considered. Total wood fuel consumption is probably three times that usually shown in statistics, and about half of the world's population relies mainly on wood for their cooking (four-fifths of total household energy use) and heating. Furthermore, supply statistics of non-commercial energy can be out by factors of 10 or even 100.

The so-called 'second energy crisis' has arisen as a result of the diminishing supplies of non-commercial or traditional fuels such as wood, dung and straw. This has led to increasing deforestation, damage to ecosystems and rural poverty. Fuels-from-biomass programmes are now being considered in many developed and developing countries of the world but the biggest difficulty with implementing them seems to be the simplicity of the idea—the solution is too simple for such a complex problem!

In the past, photosynthesis has given us coal, oil and gas, fuelwood, food,

fibre and chemicals. The relative use of these fixed carbon sources has varied over the years and will undoubtedly do so in the future. However, now with abundant oil, the products of present-day photosynthesis are mainly evident to the developed world as food. We should re-examine and if possible, re-employ the previous systems; but, with today's increased population and standard of living, we cannot revert to old technology and must instead develop new means of using present-day photosynthetic systems more efficiently.

Each year plant photosynthesis fixes about 2×10^{11} tonnes of carbon with an energy content of 3×10^{11} J; this is about 10 times the world's annual energy use and 200 times our food-energy consumption. The efficiency on land may be about 0.2–0.3% overall, whereas average agriculture may be about 0.5% efficient. These efficiencies represent stored energy and not just the initial conversion efficiencies so often quoted in other energy systems.

All the atmospheric CO_2 is cycled through plants every 300 years, all the O_2 every 2,000 years and all the H_2O every 2 million years. The magnitude and role of photosynthesis is largely unrecognised principally because we use such a small fraction of the fixed carbon and don't realise the important recycling phenomena—any interference in this latter role from pollution could have serious consequences. The increasing content of CO_2 in the atmosphere (a 25% increase over the past 125 years) has become a worrying problem. However, there is no doubt that renewable biological (and photochemical) systems for fuel production will not contribute to the atmospheric CO_2 concentration and biomass may just help alleviate some of the problems by acting as a temporary carbon sink.

Fortunately for us, plants are very adaptable and exist in great diversity—they could thus continue indefinitely to supply us with renewable quantities of food, fibre, fuel and chemicals. If the impending liquid fuel problem which is predicted within the next 10 to 15 years comes about, we may turn to

plant products sooner than we expect. Let us be prepared!

Solar/biological systems could be realised to varying degrees over the short and long term. Some, such as the use of wood, biological and agricultural wastes, and energy farming, could be put into practice immediately, whereas others may never become practicable. Photobiological systems can be tailored to suit an individual country taking into consideration total available energy, local food and fibre production, ecological aspects, climate and land use. In all cases the total energy input (other than sunlight) into any biological system should be compared with the energy output and also with the energy consumed in the construction and operation of any other competing energy producing system.

Biomass

Solar energy is a very attractive source of energy for the future but it does have disadvantages. It is diffuse and intermittent on a daily and seasonal basis, thus collection and storage costs can be high. However plants are designed to capture diffuse radiation and store it for future use. Thus there is much serious thought (and money) being given to ideas of using biomass as a source of energy—especially for liquid fuels, but also for power generation. I am aware of biomass programmes in the UK, Ireland, France, Germany, Denmark, Sweden, USA, Canada, Mexico, Brazil, Australia, New Zealand, India, Philippines, Thailand, Israel and China.

The advantages and easily identified

problems with biomass systems are summarised in Table 2; the long term advantages are however very considerable. The programmes vary in their emphasis, and show that most of the research and development should be done locally. Such R & D is an ideal opportunity to encourage local scientists, engineers and administrators in one field of energy supply. Even if biomass systems do not become significant suppliers of energy in a specific country in the future, the spin off in terms of benefits to agriculture, forestry, land use patterns and bioconversion technology are, I think, significant.

In Table 3 I have attempted to summarise biomass products and their costs to give an idea how close some technologies are to economic reality. One must be fully aware of the assumptions involved before extrapolating or drawing firm conclusions from these figures.

USA

The USA has a very large R & D programme on biomass which had a 1977/1978 budget of \$22m and a proposed budget of \$42m for 1979. Burwell in an article called "Solar biomass energy: an overview of US potential" gives a good general picture and presents some of his own ideas of the best systems for the future. The 1975 US use of energy was 71×10^{14} J; the total standing forest inventory however has an energy content three times this annual energy use. The total annual biomass growth of commercial forests is 9.3×10^{14} J of which 6.6×10^{14} J is potentially collectible. Cropland agriculture produces energy totalling about 12×10^{14} J annually of which about 40% is represented by residues left on the land. Grain crops alone produce about 7.1×10^{14} J annually of which 5.9×10^{14} J is the net collectible energy yield, 3.8×10^{14} J of this being in the form of residues. A detailed analysis of "potentially usable biomass residues" shows that of the residues currently collected, 2.1×10^{14} J could be obtained from urban solid wastes, 1.0×10^{14} J from animal feedlots, canneries, wood manufacture, and so on. Uncollected residues such as cereal straw, corn stalks and logging residues could contribute 5×10^{14} J per annum. Burwell considers that major opportunities for energy provision lie in the use of forest residues and improved management of productive forest land. He also makes the interesting point that 60% of US cropland is dedicated to the production of livestock—and this excludes the contribution that 282 million hectares (38% of mainland US area) of pasture and rangeland make to livestock support. There are thus large areas of land which could be used in the future

for the production of biomass.

The concept of intensive silviculture biomass farms or energy farms has been one subject of detailed analysis. Fast-growing deciduous trees which coppice (resprout from stumps) have been examined, as have numerous other trees including those which fix nitrogen to ammonia. The use of agricultural residues as a source of energy in the US has been the subject of another major evaluation. A national total of 430 million dry tons is available each year, made up of 280m tons of crop residues, 120m tons of residues from logging and 30m tons from animal manure. (Excluded from these figures were residues from food processing, grazing animals, and hay and forage crops.) Theoretically this residue could supply 31% of the electricity, 20% of the natural gas, or 8% of the oil requirements of the US. This is very unlikely ever to happen since at

'If the impending liquid fuel problem comes about, we may turn to plant products sooner than we expect . . . Let us be prepared'

present 20% of the residues are used and 58% are returned to the soil, leaving only 22% classified as excess. However, these percentages will change as other uses (energy, chemicals, and so on) and prices emerge. At present electricity production from residues is cost-competitive at five study areas, process steam at seven areas and synthetic natural gas (compared to propane costs) at two areas.

Another US study says that adaptive systems should be encouraged which will "modify themselves to meet evolving needs and constraints". Such adaptive systems contrast with energy farms and the use of agriculture residues—but of course, the three systems can blend into each other depending on circumstances. Thus biomass intermediates (besides food) are processed into fuels or materials depending on relative price levels. Two examples cited are corn and sugarcane production. It is "theoretically possible to reorganise the present US corn biomass system to permit the production of 10 to 18 $\times 10^9$ l of ethanol (or its equivalent in other fermentation products) while obtaining the same quantity of end-use food products in the form of beef, poultry and pork". The ethanol could be blended at 10% with a $\frac{1}{4}$ of the US gasoline. Sugar cane produces numerous byproducts such as molasses, alcohol and bagasse which can be used

for power generation, fermentable substrates and substitute wood. The study concludes that "fuels from biomass may possibly supply 10% or more of a curtailed US energy consumption" and that "knowing when and where to switch from emphasis on food and materials to emphasis on fuels is just as important as knowing how to produce the fuels."

Canada

Canadian studies on the large scale production of methanol from biomass show that by 2025 between 4 and 42% (depending on total energy use) of the transport fuels could be provided by such methanol. Methanol represents a rather unique fuel combining the portability of liquid petroleum products and the clean, even-burning characteristics of natural gas. The Federal Government recently announced a \$180m programme on biomass R & D and also provided incentives to industry to use wood and forest residues to provide energy.

Australia

In Australia, *Eucalyptus*, cassava (*Manihot*), *Hibiscus*, napier grass (*Pennisetum*) and sugarcane have been selected as potentially the most desirable high-yielding crops which can be harvested over the whole year. It was shown that alcohol produced from cassava (starch-rich) is an economically viable system, but that if processing to destroy cell walls is required the costs become too high. The cost of alcohol from cassava is calculated to be Australian \$250/tonne from a 100,000 tonne/year batch-process plant which compares favourably with the current market price of alcohol (Australian \$275/tonne) as an industrial solvent. Recent studies show that over half Australia's liquid fuel requirements could be produced from specifically-grown crops and agricultural residues.

New Zealand

With its very efficient agriculture, low population density and the fact that it uses a large proportion of its foreign exchange for petroleum purchases it is natural that New Zealand is considering biomass as a source of fuels. Current work shows that fodderbeet for ethanol and wood for methanol may be economic sources of liquid fuels.

Philippines

A feasibility study has shown that a 9,100 hectare fuel wood plantation "would supply the needs of a 75 MW steam power station if it were not more than 50 km distant". The investment requirements and cost of power produced looks favourable and competitive with oil-fired power stations of similar capacity. The best species of fast growing tree seems to be the "giant ipil-ipil" (*Leucaena leucocephala*) which fixes

Fodder beet in New Zealand: ideal for fermentation to alcohol.

nitrogen to ammonia.

Europe

In Europe a number of countries are conducting feasibility studies of the potential which biomass may have for supplying a source of energy and fuels in the future. Trial plantings of alder, willows, poplars, etc. are being undertaken in addition to assessing energy yields from agricultural residues, urban wastes, techniques of conversion, waste land and forest potentials and algal systems.

Little has been published as yet but a recent study (Project Alter) in France by "Le Groupe de Bellevue" proposes that in the long term France could produce liquid and solid fuels, comprising 11% and 14% of its total energy requirement respectively, from biomass sources. Land use constraints will be a problem but considering Europe as a whole, its past vegetation history, with its diverse climates and land use patterns, and its already burgeoning food (including liquid) surpluses there may be far greater potential for biomass production than is commonly imagined.

Brazil

By far the most ambitious biomass programme which has been planned is that in Brazil for the production of alcohol from sugar cane, sorghum, cassava and other crops. This National Alcohol Programme (PNA or Proalcool) was established in November 1975. The alcohol will be used to blend with petrol—a mixture of up to 20% (by volume) requires no adjustment to the engine (over the past 10 years the State of Sao Paulo with over 1.3 million cars has varied the alcohol content of its petrol from 0.4 to 13.5%—and 18% in 1978—depending on the availability of alcohol and price of molasses). Up to August 1977, 141 new alcohol distilleries were authorised by Proalcool which would require an investment of about \$900m and would supply 3.2×10^9 litres of alcohol by 1980, about a fifth of the projected gasoline requirement. By 1985 total production of alcohol could reach 5 to 10×10^9 litres with a total investment of about \$3.15 billion. An economic

analysis of the production of alcohol from sugar cane and cassava calculated selling prices as fuel, ex-distillery, of \$0.33/1, 81% of the present retail price of gasoline on a volume basis. Brazil is clearly embarking on an ambitious programme of fuel import substitution using the natural advantages of land and climate which it has—and it may be a very useful demonstration to other countries. The indirect benefits such as saving foreign exchange, creating new employment, encouraging domestic technology and industry, and reducing pollution, are great.

Sahel region

The problem of deforestation and desertification has highlighted the lack of fuelwood in most countries of this region. It is a scarcity which is reaching crisis proportions in large parts of South Asia, the Sahel, Andean countries, Central America and the Caribbean.

The per capita requirement for cooking alone is about 0.5 m³ of wood/year. Total fuelwood requirement is probably about 1 ton which is equivalent to about 400 kg coal per person per year—equivalent of a 3 inch lump of coal per person per day. Demand from urban areas and industry to use char-

coal instead of the more expensive kerosene and oil is diverting woodfuel from rural areas, resulting in increasing forest and scrub destruction (often long distances from villages) and use of dung as a fuel instead of as a fertiliser. A recent Dutch study of the Sahel region points out two possible solutions: decreasing fuelwood demand by using stoves which reduce consumption by 70%, and increasing the supply of fuelwood by establishing "forest plantations". Costs of reforestation and fuelwood production have been calculated for the tree species suggested and the conclusion is that "under the conditions assumed it is an economically feasible activity". Naturally there are institutional problems which impinge on agriculture and other practices of the society but if such countries are to achieve even a modicum of internal fuel production they should seriously consider such biomass systems and set up fuelwood plantations as soon as possible.

India

A study in Tamil Nadu, South India, on the possibility of growing Casuarina (a nitrogen fixing tree) as a source of fuel for a power plant generating 100 MW electric has shown favourable

Table 1 Fossil fuel reserves and resources, biomass production and CO₂ balances

Proven reserves						Tonnes coal equivalent

Gas	..	..	..	..	..	1×10^{11}	
						$8 \times 10^{11} \text{t}$	$= 25 \times 10^{21} \text{J}$
Estimated resources						Tonnes coal equivalent	
Coal	..	..	..	..	..	85×10^{11}	
Oil	..	..	..	..	..	5×10^{11}	
Gas	..	..	..	..	..	3×10^{11}	
Unconventional gas and oil	..	..	..	..	..	20×10^{11}	
						$113 \times 10^{11} \text{t}$	$= 300 \times 10^{21} \text{J}$
Fossil fuels used so far (1976)	..	..	..	..	..	$2 \times 10^{11} \text{t carbon}$	$= 6 \times 10^{21} \text{J}$
World's annual energy use	..	..	..	..	..		$3 \times 10^{20} \text{J}$
							$(5 \times 10^9 \text{t carbon from fossil fuels})$
Annual photosynthesis							
(a) net primary production	..	..	..	..	..	$8 \times 10^{10} \text{t carbon}$ $(2 \times 10^{11} \text{t organic matter})$	$= 3 \times 10^{21} \text{J}$
(b) cultivated land only	..	..	..	..	..	$0.4 \times 10^{10} \text{t carbon}$	
Stored in biomass							
(a) total (90% in trees)	..	..	..	..	..	$8 \times 10^{11} \text{t carbon}$	$= 20 \times 10^{21} \text{J}$
(b) cultivated land only (standing mass)	..	..	..	..	..	$0.06 \times 10^{11} \text{t carbon}$	
Atmospheric CO ₂	..	..	..	..	..	$7 \times 10^{11} \text{t carbon}$	
CO ₂ in ocean surface layers	..	..	..	..	..	$6 \times 10^{11} \text{t carbon}$	
Soil organic matter	..	..	..	..	..	$10-30 \times 10^{11} \text{t carbon}$	
Ocean organic matter	..	..	..	..	..	$17 \times 10^{11} \text{t carbon}$	

These data, although imprecise, show that (a) the world's annual use of energy is only 1/10 the annual photosynthetic energy storage, (b) stored biomass on the Earth's surface at present is equivalent to the proven fossil fuel reserves, (c) the total energy stored as fossil carbon only represents about 100 years of net photosynthesis, and (d) the amount of carbon stored in biomass is approximately the same as the atmospheric carbon (CO₂) and the carbon as CO₂ in the ocean surface layers.

economic and social benefits. In direct competition with coal a payback period for such an energy plantation would be from 15 to 30 years. An equivalent of 110 hectares is required to generate 1 MW electricity; about 11,000 labourers would be required, and the overall energy output/input ratios are high.

China

During the 1970s biogas plants have been perfected and installed at a rapid rate. It is estimated that there are now (1977) 4.7 million in operation and the methane so produced is used for cooking, crop drying, power generation and various other purposes. In Szechwan province alone, 17 million people use biogas for cooking and lighting; in some areas 80% of all rural households are served by biogas.

Algal systems

The idea of using algae and bacteria in biological solar energy systems is not new but has received more serious attention over the past few years. One advantage of such microbial systems is that they can be technologically sophisticated or simple depending on local conditions.

Many liquid and semi-solid wastes from houses, industries and farms are ideal for the growth of photosynthetic algae and bacteria, and under good conditions rapid growth with about 3–5% solar conversion efficiency can be obtained. The harvested algae may be fed directly to animals, fermented to produce methane, or burnt to produce electricity. Simultaneously, waste can be disposed of and water purified; it is estimated that such algal systems are half to three-quarters as expensive as conventional waste disposal systems in California. The harvested biomass can be fermented to methane, while the residues would contain virtually all the nitrogen and phosphorus of the algal biomass, so providing a good agricultural fertiliser. One acre of algal

The Sahel: scarcity of firewood has reached crisis proportions.

ponds could supply the fertiliser required by 10 to 50 acres of agriculture.

Future photosynthesis

One of the 'problems' with photosynthesis is that it requires a whole plant (or alga) to function—and the problem with whole plant photosynthesis is that its efficiency is usually low (less than 1%) since many limiting factors of the environment and the plant itself interact to determine the final overall efficiency. Thus a task for photosynthesis of the far future is to try to select and/or manipulate plants which will give higher yields with acceptable energy output/input ratios. We need much more effort placed on studies of whole plant physiology and biochemistry and their interactions with external (environmental) factors. Already this type of research is being increasingly funded by both industrial and government organisations.

Examples of the type of research which is being done or needs to be done are: photosynthetic mechanisms of carbon fixation; factors in bioproductivity; genetic engineering using plant cell tissue cultures; plant selection and breeding to overcome stresses (drought, temperature or salinity); selection of plants and algae with useful products such as oil, glycerol, waxes, or pigments; nitrogen fixation and metabolism and its regulation by

photosynthesis.

Synthetic photosynthetic systems and photochemistry

Since whole plant photosynthesis operates under the burden of so many limiting factors (internal and external) would it be possible to construct artificial systems which mimic certain parts of the photosynthetic process and so produce useful products at higher efficiencies of solar energy conversion? (A 13% maximum efficiency of solar energy conversion is considered a practical limit to produce a storable product). I think that this is definitely feasible from a technical point of view but it will take some time to discover whether it could ever be economic. Plants in fact perform at least two unique reactions upon which all life depends and which have not yet been emulated in artificial (synthetic) systems: the splitting of water by visible light to produce oxygen and protons (hydrogen) and the fixation of CO₂ into organic compounds.

Photosynthesis is the key process in the living world and will continue to be so for the continuation of life as we know it. The development of photo-biological energy conversion systems has long-term implications. We might well have an alternative way of providing ourselves with food, fuel fibre and chemicals in the next century.

Suggested time-table

for recommendations

● *Next 10 years*—fuels from residues, trees and existing crops; more efficient use of existing biofuels; demonstrations and training.

● *10–20 years*—increased residue and complete crop utilization, local energy crops and plantations in use.

● *After 20 years*—energy farming; improved plant species; artificial photo-biology and photochemistry. □

Table 2 Biomass systems

Advantages	Problems
1. stores energy for use at will	1. land use competition
2. renewable	2. land areas required
3. dependent on technology already available, with minimum capital input	3. supply uncertainty in initial phases
4. can be developed with present manpower and material resources	4. fertilizer, soil and water requirements
5. reasonably priced	
6. ecologically inoffensive, and safe	
7. does not increase atmospheric CO ₂	

Table 3 Predicted biomass energy products costs compared to conventional—USA (1981 \$)

Product	Cost from biomass (\$/10 ⁶ BTU)	Conventional cost (\$/10 ⁶ BTU)	Biomass Conventional
Methanol	8.4–15.9	8.4	1.0–1.9
Ethanol	15.0–36.3	19.6	0.8–1.9
Medium BTU gas ..	4.7– 7.4	3.0–5.0	0.9–2.5
Substitute natural gas	4.8– 7.3	3.0–5.0	1.0–2.4
Ammonia	5.8–11.4	7.4	0.8–1.5
Fuel oil	3.6– 7.9	3.2	1.1–2.5
Electricity	0.03–0.14(\$/KWH)	0.03–0.06(\$/KWH)	0.5–4.5

Jobs gloom: a military solution?

SIR,—The problems of job opportunities and job security in science are serious (21/28 December, page 743). But solutions which may be highly desirable for individuals may be disastrous for science itself. While there are many exceptions, for most scientists the decline in research productivity between the years of 35 and 45 is unequivocal. Unfortunately this decline is only rarely matched by a compensating increase in teaching or administrative skills.

Although it may be anathema to most scientists to look to the military for an answer, I suggest that in this area it has much to teach us. Anyone becoming an army officer accepts that the career grade is Major and that, depending on the country concerned, those who are not promoted above this grade will retire between 40 and 45. Each level of promotion buys a few extra years until Field Marshals are appointed for life. A similar system in science would provide a long term solution to the present ills. It would work as follows.

Far more junior posts than are at present available would be created but these would automatically terminate at age 40. A gratuity equal to three years salary or a modest pension would then be provided. Retirement could be taken as early as 35 when a one year gratuity would be given.

Promotion above the basic career grade would depend on a realistic assessment of research, teaching and administrative contributions. Each promotion rung would buy an extra five years. Perhaps half the entry would be eliminated at the first hurdle and another half at the second, with relatively little attrition thereafter. The few highly productive scientists who remain active into old age would become 'Field Marshals' and would not be expected to retire.

The advantages of this system are many. As in the army, people would enter science knowing that unless they did very well their career would end at 40. This would eliminate the unenthusiastic at the beginning and provide a notable stimulus to research. Many junior posts would be available and the system would not be wrecked by a preponderance of individuals making little or no contribution. Institutions would not be reluctant to make early appointments for fear of having to maintain a person's employment until 65 or 70. In most cases scientists would know by the age of 35 whether or not they were going to be successful and could then begin to plan second careers in the comfortable knowledge that they would have three years in which to make adjustments. As with the military, organisations would develop which specialised in placing scientists in appropriate positions in industry or government. Industry, government, and hence science would all benefit from this influx of people with a genuine scientific background and not simply a first degree in science.

I do not underestimate the anguish

such a system would cause in the transition period. But some such radical approach is essential if we are not to replace the current problems of individuals by the much more serious one of an almost totally stagnant scientific community.

Yours faithfully,

DAVID F. HORROBIN

No rabies virus at Glasgow

SIR,—I should be grateful for the opportunity of correcting an error which has appeared in your journal (11 January, page 81). This was a statement in which the Department of Virology at the University of Glasgow was cited as a laboratory holding a Category A Pathogen, namely rabies, as at 12 December 1978. This, I am happy to tell you, is not the case, as the small stock of rabies virus held by that department was destroyed in June 1977. It had, in fact, never been used for active research, and had remained in deep freeze for eight years before being destroyed.

I imagine that your source of information for this article was the draft of the Shooter report. I am informed by the Scottish Home and Health Department that they anticipate being able to update and correct this situation before the report is finally published.

Your faithfully,

ANDREW D. RANKINE

Reassess hazards of recombinant DNA

SIR,—The comments (15 February, page 509) by a committee of the Royal Society on the recent published statement of the Genetic Manipulation Advisory Group will be widely welcomed and supported. However, I should like to comment on one of the suggestions they make.

It is argued that there is an urgent need for more research to evaluate the risks associated with the ingestion of organisms containing recombinant DNA. Before devoting yet more resources to the general hypothesis that recombinant DNA synthesised *in vitro* poses novel hazards to man, is there not a prior need to reconsider in which areas of recombinant DNA research there remain sound arguments indicating that the hypothesis should be taken seriously? The committee has properly criticised the Genetic Manipulation Advisory Group for publishing what are often called hazard scenarios without adequate argument or evidence supported by citation of relevant literature. But could not a similar criticism be made with equal validity against the hazards hypothesis in its entirety? The report of the working party chaired by Lord Ashby which was set up to evaluate this hypothesis made a number of assertions in favour of it but none of them was documented in the way the Royal Society committee advocates. Admittedly this report was written in response to the possibilities suggested in

the Berg letter were more emotional than rational. All the more reason, now that four years have passed, for a cool reassessment of the questions before we embark on experimentation.

The most urgent need in 1979 surely is for a re-examination of the hazards hypothesis to determine which, if any, aspects of it remain credible enough to deserve further attention on scientific grounds. This reassessment can only begin if those who remain convinced of hazards are prepared to state their case in published form with the rigour urged by the Royal Society committee, and in a manner that permits rebuttal like any other scientific argument.

If such a reassessment suggests that areas of significant risk remain then let us devote resources to quantifying the risks in these areas. If, on the other hand, this reassessment suggests that the hypothesis is unfounded or if no one is prepared to argue the case to the contrary, then should not those biologists who have collectively exploited their authority to open the so-called debate on the hazards of genetic engineering be urged to use their authority to close it in like manner. The danger in what the Royal Society proposes is that it could lend further weight to a hypothesis that may not deserve it.

Yours faithfully,

R. H. PRITCHARD

University of Leicester, UK.*

Energy forecasts mislead

SIR,—Your discussion of energy forecasts (18 January, page 162) misses the point. It is easy to forecast a low consumption of energy, and all too easy to make this forecast come true. The price of nuclear powered electricity has risen partially because of delays caused by those predicting low consumption of energy; as a result, demand has fallen. In a recent visit to England I noted that the head of a small college lived in a house I rejected as unsuitable as a research lecturer in 1952. This contraction in housing standards, and with it a contraction in demand for fuel, has reached other parts of society in the past few years.

The challenge is not to predict a low energy consumption and make it come true; but to work toward a just society, where the well being and convenience we have often correlated with energy consumption can be achieved with minimum financial, ecological and environmental costs. None of these costs have a one-to-one relationship with energy production or consumption, and to argue otherwise may be counter-productive. Those energy producers who concentrate solely on meeting "demand" have led us astray. Those who, like Mr Leach, are constantly trying to tell us that we don't need as much are equally guilty of keeping our concentration in the wrong place.

Yours faithfully,

RICHARD WILSON

news and views

It is only five years since the first reports that lymphoid cells from unimmunised mice were able to kill certain lymphoid target cell lines (Herberman *et al. J. natn. Cancer Inst.* 51, 1509, 1973). Since then, despite a deluge of papers dealing with the phenomenon, both in rodents and in man, little solid evidence has emerged to convince the cynical immunologist that this spontaneous or natural killing has the three attributes of immunological respectability—specificity of effect, specificity of immunisation, and specific memory. Moreover, the popular term, 'natural' killing only serves now to remind us how little is really understood of the role in nature of this function so readily studied *in vitro*.

Early results suggested that natural killer (NK) effector cells in the mouse lacked surface markers of both thymus-derived (T), and bone-marrow-derived (B) lymphocytes, and were neither phagocytic nor adherent to plastic. This null cell appeared to lyse preferentially lymphoid tumour cells expressing antigens coded by RNA tumour viruses (retraviruses), leading to the suggestion that NK cells were an *in vivo* surveillance mechanism against retravirus-induced tumours. For tumour immunologists this was an attractive hypothesis as it provided a substitute for the discredited T cell as a surveillance mechanism.

As is so often the case, unfortunately, later data have complicated the issue. No firm answers have yet emerged as to the nature and origin of the NK cell, the genetic control of its activity, or its specificity of killing, activation or memory. Nevertheless, recent results have brought some order into a picture that at one time seemed to be degenerating into cytotoxic anarchy.

In the mouse, Herberman and his colleagues have suggested that NK cells express low amounts of surface markers characteristic of T lymphocytes (Herberman *et al. J. Immun.* 121, 304; 1978). Others, however, using even highly potent monoclonal anti-T cell antibodies, have not confirmed this. In any case, although the mouse Thy-1 antigen reportedly present on NK cells is characteristic of T and not B lymphocytes, it is also expressed in brain and other tissues, and its presence on NK cells would not necessarily link the NK effector with the T cell differ-

Killing comes naturally

from Peter Beverley & Dick Knight

tiation pathway. More persuasive in regard to the origin of the NK cells, however, are the observations that they carry a surface marker not present on T or B cells (although identified by a contaminant antibody in the anti-T cell serum anti-Lyt-1) and that the mutant *beige* mouse, which has deficient granulocyte function but normal T and B lymphocytes, has very low NK activity (Roder & Duwe *Nature* in the press).

In the human, recent work from Good's laboratory, as well as confirming the consensus that human NK cells possess receptors for the Fc portion of immunoglobulin, has suggested that both T and non-T cells are cytotoxic in NK assays (Gupta *et al. Proc. natn. Acad. Sci. U.S.A.* 75, 5137, 1978). Moreover, suggestions are emerging that different target cells are differentially susceptible to the action of different effectors. In the mouse too, Stutman has recently described an NC (natural cytotoxic) cell with slightly different phenotypic properties and distinctly different killing preference to the classic NK cell (Stutman *et al. J. Immun.* 121, 1819; 1978). If these results are confirmed, it becomes clear that both in mouse and man more than one effector cell may mediate 'natural' killing. In addition, since no convincing evidence for T-cell-mediated 'natural' killing has yet been presented for the mouse, a genuine species difference in effector compartments may exist.

Specificity can only be truly defined when the target antigens have been characterised. On the NK-susceptible mouse lymphoma target, YAC-1, three 'target structures' of molecular weights 130,000, 160,000 and 240,000, and distinct from known viral or histocompatibility antigens, have recently been identified (Roder *et al. Proc. natn. Acad. Sci. U.S.A.* in the press). On other targets, the available evidence from competition and monolayer absorption experiments suggests a broad selectivity of killing for groups of target cells as opposed to totally indiscriminate aggression. The emergence

of multiple NK effector populations, with apparent target preferences, especially in man, suggests further that not all NK cells will turn out to have the same range of specificities. However, the important question remains unresolved as to whether the observed selectivity reflects recognition of a limited number of ubiquitous antigens (and a fetal calf serum-derived antigen now seems unlikely), or the activity of many effector clones each recognising a single antigen.

What of specificity of immunisation? It is now clear that a variety of agents given *in vivo*—bacteria, viruses and tumour cells—can boost NK in mice. Interestingly, only those tumour cells themselves susceptible to NK lysis are able to augment NK activity in this way. A similarly wide range of agents boost NK *in vitro*, although the identity of the effectors of broad spectrum lysis induced after a period of culture with classical spontaneous NK, has not been proved. Recent work from Trinchieri and Santoli has shown, however, that *in vitro* inducers share the property of stimulating interferon release, and indeed, that interferon itself is a potent NK boosting agent (Trinchieri & Santoli *J. exp. Med.* 147, 1314; 1978). No data has yet been presented on whether interferon is the only final common path of NK augmentation, or whether boosting *in vivo* and *in vitro* have the same mechanism.

Irrespective of whether interferon affects NK cells directly or works through an intermediate cell, it seems that the augmentation is the expression of a higher level of activity already programmed into the NK cells. This program depends not on the environment of the cell donor, but on its genetic constitution, since transfers of bone marrow cells (containing NK cells) between different mouse strains show that the transferred cells retain the level and spectrum of activity of the donor strain.

Genes controlling NK activity have been mapped close to genes controlling rejection of parent-into-F₁ bone marrow grafts and close to H-2D. Intriguingly, products of this latter locus are critical for target cell recognition in classical T-cell cytotoxicity. However, natural killing is not confined by self or even species recognition. If T cells are confirmed as an NK effector population, it is somewhat surprising that their

activity seems to have no MHC restriction.

Does this new information on the nature, specificity, and genetic control of the NK cell allow any tentative conclusions as to its function *in vivo*? Certainly data exist correlating tumour incidence and the ability to reject tumour grafts with the level of NK activity. Moreover, there seems to be a reciprocal relationship between T cell and NK activity, as athymic nude mice and thymectomised animals have higher levels of NK than intact syngeneic mice. The data from Kiessling's group, reported in this issue of *Nature* (page 174), showing that a subset of thymo-

cytes can be killed by NK cells, and correlating the presence or absence of this subset with the level of NK activity, also suggests that regulation of NK and T cells is closely connected. Should this subset of thymocytes turn out to be particularly susceptible to reovirus-induced transformation, then the surveillance and immunoregulatory theories could be neatly fused. □

A two-dimensional superfluid?

from P. V. C. McClintock

Has two-dimensional superfluidity been observed? There has been a continuing controversy as to whether or not this interesting phenomenon, predicted theoretically for ideal two-dimensional systems, has been seen in real liquid helium-4 films. Dash has argued persuasively (*Phys. Rev. Lett.* **41**, 1178; 1978) that it has not; and that the experiments which had apparently demonstrated the effect were misinterpreted. Some new measurements now reported by Webster, Webster and Chester of the University of California at Los Angeles (*Phys. Rev. Lett.* **42**, 243; 1979) seem, however, to have tilted the balance of the evidence back in the affirmative direction once more, in favour of the original interpretation.

The superfluidity of the 'creeping film' which forms on surfaces dipping into liquid helium has, of course, been well known—and intensively studied—ever since it was first discovered by Rollin in 1936. It is this phenomenon which is responsible for the famous demonstration of superfluidity in which an open-topped cup of liquid helium is able to empty itself while remaining upright, using the film as a kind of syphon. The present interest centres, however, on very thin helium films: so thin, in fact, that no parameter can change within their thickness, and hence nothing can happen in the dimension at right angles to the surface on which the film is adsorbed. Such films probably constitute what are effectively two-dimensional (2-D) systems.

The theory of 2-D helium has made rapid progress in recent years under the

stimulus, particularly, of the beautiful experimental work carried out by Dash and his co-workers at the University of Washington, using exfoliated graphite as a substrate. A striking prediction made by Nelson and Kosterlitz (*Phys. Rev. Lett.* **39**, 1201; 1977) was that, if a 2-D system undergoes a superfluid transition, it will do so in a precipitous jump: the superfluid fraction ought to jump discontinuously from zero to a finite value, ρ_s^* . This is in sharp contrast to what happens in three dimensions. When ordinary bulk liquid helium undergoes the transition, the fraction of the liquid which behaves as superfluid increases continuously from zero. Nelson and Kosterlitz concluded, furthermore, that for a 2-D liquid helium-4 film the jump should be universal: that is, the ratio of ρ_s^* to the absolute temperature T_0 at onset should be quite independent of the nature of the substrate, of the coverage at which the transition takes place, or indeed, of virtually anything else.

Apparent experimental verification of this remarkable prediction was reported shortly afterwards: by Rudnick, on the basis of third sound measurements (*Phys. Rev. Lett.* **40**, 1454; 1978); and by Bishop and Reppy, based on their measurements of the superfluid fraction on a vibrating substrate (*Phys. Rev. Lett.* **40**, 1727; 1978). The latter type of measurement seems at first sight to give a particularly direct and unambiguous measure of the superfluid fraction. The period of the oscillator is dependent on its mass, and thus on the effective mass of the adsorbed helium film sticking to it; but, if some proportion of the film is superfluid then, instead of following the oscillations, this fraction will just slip, and therefore will not affect the measured

period. Values of ρ_s^*/T_0 deduced in this way were in excellent quantitative agreement with Nelson and Kosterlitz's prediction.

Dash argued, however, that the superfluid onset as measured by this technique does not represent genuine 2-D superfluidity. He suggested, first, that inhomogeneities in the Mylar substrate would cause the formation of 'puddles' of helium where the film was relatively thick, with interconnecting regions of thinner film. The observed superfluid onset therefore represented, not 2-D superfluidity in the film as a whole, but merely the occurrence of superfluidity in a sufficient proportion of the interconnecting regions. By this time the deep 'puddles' would, of course, correspond to 3-D superfluid. Second, he suggested that even if the substrate did provide an ideal atomically flat surface (which he doubted), the films themselves would be non-uniform. He envisaged that, as helium atoms were gradually added to the substrate, at a fixed temperature, they would first form a 2-D gas; but that, when a certain critical coverage was reached, interactions between the atoms would result in the formation of small patches of 2-D liquid surrounded by the 2-D vapour. As further atoms were added the connectivity of the liquid regions would eventually provide a continuous 2-D path across the whole experimental area and, if the temperature was low enough, superfluidity might then appear abruptly: the superfluid fraction at onset could clearly be non-zero, corresponding in fact to that of the liquid regions immediately before their being connected together.

In the experiment now reported from UCLA, the Websters and Chester have performed another vibrating substrate measurement, using an oscillating quartz crystal. The important difference from earlier work is that they have added an additional variable parameter to the system by mixing up to 30% of helium-3 with their helium-4: a proportion of helium-3 has a profound effect on the superfluid transition in helium-4, depressing it to lower temperatures and even eliminating it altogether if too much is added. Nonetheless, it turned out that the value of ρ_s^*/T_0 was completely unaffected by the helium-3, remaining closely equal to the universal constant predicted by Nelson and Kosterlitz—although, of course, ρ_s^* and T_0 were individually changed to a considerable degree. So, for some as yet unexplained reason, Dash's arguments do not seem to be applicable in practice.

These latest results constitute compelling evidence in support both of the theory and of the belief that the helium-4 film at onset really does behave as a two-dimensional superfluid.

Purine insertase: a new enzyme

from Gerard O'Donovan

It is now generally believed that a large number of environmental agents cause damage to DNA. Even in the absence of environmental stimuli DNA has to cope with yet another type of damage, namely the formation of DNA apurinic/apyrimidinic sites (AP sites). These lesions are produced spontaneously by the loss of purine or pyrimidine bases from the DNA and also by the action of a specific class of enzymes known collectively as DNA N-glycosylases (previously known as N-glycosidases). Three distinct enzyme activities have been discovered to date. These N-glycosylases remove uracil (Lindahl *Proc. natn. Acad. Sci. U.S.A.* **71**, 3649; 1974), 3-methyl adenine (Laval *Nature* **269**, 829; 1977; Riazuddin & Lindahl, *Biochemistry* **17**, 2110, 1978), or hypoxanthine (Karran & Lindahl, *J. biol. Chem.* **17**, 5877, 1978) from DNA without perturbing the sugar-phosphate backbone.

Until recently these enzymes were called DNA N-glycosidases because traditionally the base-sugar bonds in nucleic acids which they cleave, were termed glycosidic bonds (Lindahl, *Proc. natn. Acad. Sci. U.S.A.* **71**, 3649; 1974). However, the current rules for carbohydrate nomenclature (*Biochemistry* **10**, 3983, 1971) state that a glycosidic bond is a linkage through oxygen obtained by replacement of the hydrogen atom of the hemiacetal hydroxyl group, while removal of the entire hydroxyl group results in a glycosyl bond (Riazuddin & Lindahl *op cit*).

Deoxyribonucleases that act on DNA containing apurinic sites have been characterised from various sources including bacteria (Gossard & Verly *Europ. J. Biochem.* **82**, 321, 1978), plants (Thibodeau & Verly *J. biol. Chem.* **252**, 3,304; 1977) and human cells (Kuhnlein *et al. Nucl. Acids Res.* **5**, 951, 1978). These enzymes are part of a duplex DNA repair pathway in which the apurinic endonuclease (AP endonuclease) makes an incision in the vicinity of the apurinic lesion, then the apurinic lesion is excised by an appropriate exonuclease and the resulting gap is filled in with a DNA polymerase before closure with DNA ligase. The apurinic lesion presumably arose spontaneously, by reaction with chemicals or as the product of a DNA N-glycosylase, one of the enzymes described above which removes ab-

normal bases from DNA by hydrolysing the glycosyl bond.

Since excision repair is a multi-enzyme process it seems reasonable that a simpler and more straightforward pathway might exist. With respect to modified DNA, N-glycosylolytic removal of abnormal bases from DNA to produce an AP site, with the concomitant reinsertion of the correct base, has been speculated on. In a recent issue of *Proc. natn. Acad. Sci. U.S.A.* (**76**, 141, 1979) Deutsch and Linn report the discovery of an enzyme activity from cultured human fibroblasts which seems to reinsert purines, but not pyrimidines, into DNA containing apurinic sites. The activity, which is partially purified (molecular weight 120,000) to be free from apurinic endonucleases, was first identified by its ability to bind specifically to partially depurinated DNA. Using radioactively labelled purines, Deutsch and Linn show that the free base is best utilised, and that the incorporation like the binding, is specific for DNA apurinic sites. Moreover, using depurinated synthetic polymers, they show that the insertion of purine bases seems to be template-specific, with guanine but not adenine being inserted into depurinated poly (dG-dC), and adenine but not guanine being inserted into poly (dA-dT).

The formation of a glycosyl bond would seem to require energy although the free energy of formation within a DNA molecule has not been measured directly. In the present study the reaction occurs in the absence of any obvious energy source. One suggestion offered by Deutsch and Linn for the free energy source in the case of a free purine substrate is the reforming of base pairs and stacking at the site of the reaction. With respect to an energy source, it is significant that another reaction in which the guanine base is utilised also occurs in the absence of energy. Here, the tRNA guanylylating enzyme replaces the Q base of certain tRNAs with guanine (Okado *et al. Nucl. Acids Res.* **3**, 2,593, 1978, Farkas & Singh, *J. biol. Chem.* **248**, 7,781; 1977).

Clearly the most likely role for the AP endonucleases is in DNA repair. Such enzymes (purine base insertases) might be extremely active in repair during normal DNA replication. But because they are present in nature in such large amounts, almost universally, it is tempting to ascribe additional roles to the AP endonucleases. As pointed out by Deutsch and Linn it could be that the utility of base insertion may not be for DNA repair but rather for situations in which the generation of genetic diversity is desirable. In addition, the eukaryotic genome contains large numbers of modified bases which

could be replaced (or inserted) as a regulatory or developmental signal. Such hypotheses are simple to formulate but difficult to prove; it will be of interest to see if future investigations unmask more exotic DNA N-glycosylases and perhaps related insertases.

A surplus of carbon dioxide

from G. Skirrow

Two recent independent contributions (Brewer *Geophys. Res. Lett.* **5**, 997, 1978, Chen & Millero *Nature* **277**, 205; 1979), both based on analysis of Geosecs data, have outlined direct experimental evidence that part of the present, continuing, atmospheric CO₂ increase consequent on fossil fuel combustion is being transferred to the sea and that this process has probably been taking place for some time. Although it has always seemed reasonable to suppose that this transfer did occur, evidence has hitherto been mainly indirect and estimates of the extent of the exchange have relied on, for example, observations of the distribution of ¹⁴C produced by nuclear bomb explosions.

The air-sea transfer of CO₂ is merely one facet, albeit an important one, of the global carbon cycle. Briefly, CO₂ is gained by the atmosphere through volcanic exhalations, by evasion from the sea and by respiration and combustion. It is lost from the atmosphere by invasion into the sea, by photosynthesis into the terrestrial and marine biospheres and by weathering processes leading to dissolution of, particularly, carbonate rocks and the transfer to the sea of HCO₃⁻-rich solutions by continental run-off. Within the oceans biogenic precipitation of CaCO₃ from the supersaturated surface waters (together with precipitation of some organic debris) transfers some carbon to the sediments, although some of the CaCO₃ dissolves during its descent in the oceans. Over geological periods of time sea-floor spreading makes the sediments available for reworking. A more detailed examination shows that the carbon cycle is intimately linked with those for other elements, notably calcium, oxygen and nutrients.

Although life forms on Earth have changed over the past few hundred million years, the general and continuous persistence of life has been taken to imply that, over this time, the various elemental cycles have never been very violently perturbed from

G Skirrow is in the Department of Inorganic, Physical and Industrial Chemistry, Liverpool University.

G O'Donovan is an Associate Professor in the Department of Biochemistry and Biophysics, School of Agriculture, Texas A & M University

their steady states and that they have an essential stability deriving from in-built negative feedback or buffering mechanisms (Garrels *et al.* *Amer. Sci.* **64**, 306; 1976). Of course, many minor perturbations have occurred in the past although these have evidently not been sufficient to destroy life totally. However, even minor fluctuations may have consequences which, if not devastating, may be distinctly uncomfortable from a 20th century human standpoint. Thus, possible climatological changes may ensue. Quite apart from academic and intellectual reasons for wishing to understand more fully the natural processes of atmospheric and marine circulation and elemental cycle stabilisation, self-interest clearly justifies investing time, effort and money in monitoring the carbon system and in developing theoretical and modelling approaches intended to have interpretative or predictive value.

It is generally accepted that fossil fuel consumption is the main cause of the atmospheric CO_2 increase over the past century, although other human activities (deforestation and changing land usage) probably play a not insignificant part (Woodwell *Scient. Amer.* **238**, 34; 1978). However, there is no doubt about the reality of the partial pressure P_{CO_2} increase; precise and detailed measurements from many sites throughout the world over the past two decades (for example, Pales & Keeling *J. geophys. Res.* **70**, 6053; 1965) have shown that since 1958 atmospheric CO_2 has increased by about 6% and that the present atmospheric partial pressure of about 340×10^{-4} atm is some $50\text{--}60 \times 10^{-4}$ atm greater than that of a century ago. Precise knowledge of the CO_2 levels before 1850 (the effective start of the Industrial Revolution) is lacking but a value of about 290×10^{-4} atm is generally assumed. It is interesting to note that the observations made by Brewer and by Chen and Millero are at least not inconsistent with this picture, although at present the levels of precision imposed by the need to correct their basic data to allow for *in situ* CO_2 generation rules out definitive pronouncements.

The rate of increase of P_{CO_2} has increased with time in a manner matching the usage of fossil fuels, although a large fraction of the output has passed into other sinks—presumably the sea. The present annual rate of increase of P_{CO_2} is almost 1×10^{-4} atm yr^{-1} , and for the purposes of projection into the future (an uncertain business because of the likely dependence on economic factors and resource depletion) a rate of increase of something like 2% per year is often assumed (Broecker & Takahashi *The Fate of Fossil Fuel CO_2 in the Oceans*, 213,

Plenum, 1977). Sometime in the 21st century atmospheric P_{CO_2} may peak at several times the pre-industrial value (Woodwell).

Pertinent questions concern the way in which the sea responds to this increase of atmospheric partial pressure of CO_2 . That is, its capacity to moderate the increase by dissolution, the consequent changes in the chemistry of the sea, and the possibility that the attack of the now more aggressive waters on the calcite and argonite fractions of the sediments will further moderate the increase. The capacity of the sea to dissolve CO_2 is considerable although the time scale for total air-sea equilibrium is measured in centuries because of the relatively slow turnover and mixing times of the various oceanic water masses. However, according to Broecker and Takahashi who are grappling with the overall problem (including interaction with the sediments) if an injection to the atmosphere of 23×10^{16} moles of CO_2 is made, then on attainment of solution equilibrium about 70% of the injection would have passed into the sea. The effect of this uptake would be to moderate the carbonate ion concentration of the water to lead to dissolution of the CaCO_3 fractions of the sediments on certain parts of the ocean floor. Formidable problems make it difficult to quantify this general picture since these investigators have to contend not only with uncertainties concerning the future rate of industrial CO_2 generation and the rate of passage into the sea, but also with the complex kinetics of calcite dissolution (for example, Morse & Berner *Am. J. Sci.* **272**, 840; 1972). The difficulties are further compounded when it is recognised that (1) carbonate sediments are not uniformly distributed over the ocean floor, and the carbonate fraction varies considerably, falling virtually to zero for deep-sea sediments below the compensation depth; (2) the effectiveness of the carbonate fraction in neutralising the CO_2 increase depends on depth; at shallow depths the water is strongly supersaturated with respect to CaCO_3 and very high P_{CO_2} values are needed to remove this supersaturation (Skirrow & Whitfield *Limnol. Oceanog.* **20**, 103; 1975). Sediments lying between the present compensation and lysocline depths would be expected to be particularly susceptible to attack; and (3) as attack on the sediments proceeds, the remaining CaCO_3 will become more deeply buried or diluted by clay and inert materials thereby reducing the rate of attack.

Notwithstanding these discouraging considerations Broecker and Takahashi have made a start on this problem. They conclude that the potentially

available CaCO_3 in those sediments likely to be susceptible to attack is equivalent to the CO_2 derivable from the world's total fossil fuel resources and that the time constant for neutralisation of the CO_2 will be 1,500 years or less.

The studies referred to in the opening paragraph may seem a long way from those of Broecker and Takahashi, but they are different aspects of a large problem which may have important ramifications for the world as a whole. There are many grey areas in which information needs still to be collected. These include the response of the biosphere to changing atmospheric CO_2 levels, and possibly less important because of the already high levels of CO_2 in soil water, the effect this increased CO_2 will have on weathering processes. □

Making molecular catalogues

from Norman Anderson

HIGH-resolution two-dimensional gel electrophoresis, as originally described by O'Farrell (*J. biol. Chem.* **250**, 4007; 1975), has proved an extremely powerful tool for the analysis of complex protein mixtures, particularly cells. It can be made to resolve and detect quantitatively virtually all the proteins expected in *E. coli* (~ 1,500) and perhaps 2,000–3,000 of the possible 4,000–7,000 thought to occur in any given mammalian cell type. So far, however, the technique has been principally used as an adjunct to studies of particular enzymes or regulational events, and has not provided the kind of global information that might be expected to emerge from a detailed analysis of what different cells do (or at least synthesise). The reason for this is the difficulty of comparing large numbers of patterns, and of remembering enough differences to draw conclusions with regard to very large numbers of protein spots. A somewhat analogous state of affairs existed in early protein crystallography when diffraction spots could be produced on X-ray film, but the structure of the proteins producing them could not be deduced. The introduction of computers, automated densitometers, and mathematical analysis ultimately allowed such structures to be determined. This process seems to be repeating itself, but at a much higher level of complexity, in the field of high resolution two-dimensional protein mapping.

What is desired is a way of reducing

2-D gel data to quantitative lists of protein components (that is, precise spot positions and integrated densities), and ways of matching and comparing lists to deduce the rules or factors governing the synthesis of each gene product. An early and relatively easy project, for example, would be to determine the number of protein gene products common to all cell types in man, or conversely, whether proteins exist which are absolutely specific to each differentiated cell type. In order to address such questions, computer-based data reduction systems are being constructed by several groups in the US and Europe. An informal meeting at the Argonne National Laboratory reviewed progress and discussed systems design with likely major users.

J. Garrels (Cold Spring Harbor Laboratory) and N. Xuong and M. Miller (University of California, San Diego) described working systems for spot detection and integration based, respectively, on slope and contour analysis. The latter seems much faster but requires interactive help in separating compact groups of spots. In each of these systems, some progress has been made towards matching pairs of gels for comparison. Two examples of second generation dedicated mini-computer systems were described by L. Anderson and J. Taylor (Argonne) and J. Garrels (CSHL). The first segment of the two-part Argonne system (called TYCHO) involves image scanning, spot detection, and quantitation by two-dimensional Gaussian fitting, matching of patterns to compensate for small differences between gels by interactive colour television graphics, and the production of spot lists containing as many human protein gene products (PGPs) as possible. The program for searching the spot lists for correlations with the type or state of the cells producing them is called KEPLER. The Cold Spring Harbor program (called QUEST) will use virtually identical hardware but is designed primarily to compare patterns as raw image data rather than spot lists to facilitate accurate ratio quantitation in double-label autoradiographic experiments. Both systems aim to accumulate a comprehensive annotated map (or list) of proteins in a particular organism (man at Argonne and mice and rats at Cold Spring Harbor) for general research use.

An important constraint in such systems (particularly when applied to large-scale genetic work) will be processing time per gel. This is currently estimated at 20 to 60 min in the second

generation systems, depending on the number of spots. A faster image processing technology based on the Sternberg-von Neumann cytocomputer (described by P. Petraitis, Environmental Research Institute, Michigan) seemed capable of reducing processing time by at least 50%, while solid array based densitometer designs (P. Spragg, University of Birmingham, UK) offered similar improvements.

The potential use of these systems for detecting possible changes in the human background mutation rate was discussed by J. V. Neel (University of Michigan). On the basis of the current Argonne throughput of approximately 10,000 2-D gels per year, and assuming that several hundred protein gene products could be examined in each person, mutation rates could be estimated on samples as small as 30,000 individuals in a reasonable time.

Preliminary results presented by E. McConkey (University of Colorado, Boulder) indicated a wide discrepancy in average heterozygosity between major cellular proteins (as observed on 2-D gels) and the proteins of plasma and red cells (measured by classical methods). This sparked a lively debate on the effects of natural selection on different groups of proteins and brought out the view that many geneticists are still convinced that charge-change variants are better detected on starch blocks than on 2-D gels. This question was settled by the development by N. L. Anderson and B. H. Hickman (Argonne) of charge shift standards prepared by progressive carbamylation of one protein. These standards stretch all the way across the gel as a series of discrete spots, one more than the number of amino groups on the original protein, and unequivocally demonstrate the detectability of unit charge shifts.

P. O'Farrell (University of California, San Francisco) described experiments to determine whether repressed mammalian genes are indeed totally silent. Using a combination of immunoaffinity and two-dimensional separations, he was able to place an upper limit of one part in 2×10^8 on the expression of a particular protein in cells carrying the corresponding gene in a repressed state. Interestingly enough, any gene products present at this level *in vivo* are less abundant than mislabeled versions of actin and other major proteins, due to the limited fidelity of translation. There is, therefore, an irreducible 'background fog' associated with high resolution protein mapping at currently achievable sensitivities as a result of thermodynamic noise in protein synthesis.

It was generally concluded that

within the year systems will exist capable of cataloguing, comparing, and performing perturbation analyses on a good fraction of the possible products of a mammalian genome. By extending the set of observable proteins from the classically assayable (presently perhaps 2% of the total) to the most abundant 50%, we will probably be afforded a new view of many biological phenomena and, perhaps, a less welcome look at how poorly controlled present experiments are at the level of gene expression. □

Saccharin: from carcinogen to promoter

from E. Boyland

THE first indications that the widely used artificial sweetener saccharin was carcinogenic were the data of 1951 in which there was "an increased incidence of the ordinarily uncommon condition of abdominal lymphosarcoma" in rats fed saccharin¹. When the technique of implantation of pellets containing suspected direct carcinogens into the bladder of mice was introduced², it was thought that, as the bladder tissue would be less able than the liver to metabolise foreign compounds, the test would distinguish compounds that required metabolic activation from those which were directly carcinogens. The implantation of cholesterol pellets containing saccharin into the urinary bladders of a few mice induced a statistically significant incidence of tumours³. At the time we suggested that "The induction of bladder tumours with saccharin suggests that the presence of the solid pellet in the bladder may have a promoting action and that the method of bladder implantation detects incomplete carcinogens". These results with saccharin were confirmed 13 years later by experiments carried out on a larger scale⁴. Previously it had been found that saccharin had some initiating action on mouse skin⁵, and so the bladder implantation experiments in the light of knowledge at that time were interpreted as showing that saccharin was a direct carcinogen and active without metabolic activation. Subsequent investigations have been unable to detect any metabolic changes of saccharin in any of several species^{6,7}.

E. Boyland is Emeritus Professor of Biochemistry at the London School of Hygiene and Tropical Medicine.

Norman G. Anderson is Head of the Molecular Anatomy Program, Division of Biological and Medical Research, Argonne National Laboratory.

Following the bladder implantation experiments and results, at least eleven studies in which saccharin was fed to rats are available⁴; in eight of these urinary bladder tumours seem to have been induced, but in never more than 44% of rats and generally in a much lower proportion even when the diets contained 5% saccharin. In one study⁵ lymphomas and leukaemias occurred.

Saccharin may therefore be considered as a weak carcinogen for the rat bladder, by the following three criteria. (1) The dose needed to induce carcinogenesis was large—in some cases of the order of 1 kg per kg body weight. (2) The induction time was long; generally the bladder tumours appeared after at least 18 months continuous feeding. (3) Not all animals developed tumours. Potent carcinogens on the other hand induce cancer in all treated animals.

Later experiments may explain the mode of action of saccharin. When small 'initiating' doses of methyl nitrosourea (NMU) were instilled into the urinary bladder of Wistar rats which were then given either water or water containing saccharin, to drink, no bladder tumours were seen in rats given NMU without saccharin¹⁰. Only 2% of rats given saccharin alone developed bladder tumours in 95 weeks, but 57% of rats given NMU and saccharin developed tumours. Some of the rats with tumours had bladder stones but these were not considered a factor in the 'synergistic' effect of saccharin. The authors concluded that saccharin is cocarcinogenic and "that a promoting action of saccharin with cyclamate and/or other bladder carcinogens is an obvious possibility".

In another experiment the feeding of diets containing 2% FANF (N-(4-5 nitro-2-furyl 2-thiazoyl) formamide) to rats for 6 weeks induced bladder cancer in 4 out of 20 rats, but if this was followed by feeding 2% tryptophan or 5% saccharin 20 out of 39 and 35 out of 35 rats developed bladder cancer¹¹. In these experiments both tryptophan and saccharin seem to have acted as promoting agents. The result with tryptophan was similar to those in which rats fed 2-acetamidofluorene with either tryptophan or indole developed bladder tumours, whereas with 2-acetamidofluorene alone tumours at other sites were seen^{12,13}.

Further evidence that saccharin acts as a promoting agent was provided by the experiments in which cultures of C3H/10T1/2 cells, treated with non-transforming initiating doses of methylcholanthrene followed by saccharin, had a statistically significant number of transformations¹⁴. These authors estimated that saccharin probably functioned as a promoting agent, but was

1,000-fold less active than the potent promoter 12-O-tetradecanoyl-phorbol-13-acetate.

If saccharin is a promoter rather than a direct carcinogen, how can the earlier results be explained. The first bladder implantation experiments in animals showed that although the rat skin was resistant to the carcinogenic action of tar the epithelium of the rat bladder was sensitive¹⁵. Later experiments¹⁶ however, showed that implantation of paraffin wax pellets alone into the rat bladder produced a high incidence of cancer. Mice treated in the same way developed only a few bladder tumours and so could be used for carcinogen testing by this technique. The wax pellets therefore seem to be acting as promoters and rat urine or bladder epithelium may contain more material acting as initiators of carcinogenesis than does that of mice.

All the experiments in which bladder cancer has been induced by feeding saccharin have been in rats. The occurrence of these bladder tumours could therefore be due to the promoting action of saccharin together with endogenous initiators of carcinogenesis.

Several experiments therefore indicate that saccharin could be a promoting agent rather than a complete carcinogen. Saccharin is not mutagenic in the *Salmonella* reverse mutation assay of Ames or the cell transformation test of Styles and there is no indication that it is metabolised by animals or man or reacts with DNA. It has been suggested that as the carcinogenic action in rats and the dominant lethal effects in mice do not appear to be genetic; they are 'epigenetic'¹⁷. This term is a broad one and would include

promoting action, cocarcinogenesis, inhibition of DNA repair and suppression of immune reactions. The experimental data on saccharin indicate that it is a promoting agent and this is more precise than saying its effects are not produced by a genetic mechanism. The local effect of saccharin could be due to its being concentrated in urine and the bladder mucosa.

However this is not evidence that saccharin is 'harmless'. Carcinogenesis is a complex multistage process in which initiation, promotion or some other stage may be limiting steps. Thus although promoting agents are not complete carcinogens, in some conditions they facilitate cancer development which would not otherwise occur. In such circumstances, a promoter may therefore be as dangerous as a complete carcinogen. Saccharin is, however, unlikely to provide a serious hazard because the dose required to produce the promoting effect is so large—of the order of 1 kg per kg body weight. The very low though finite risks may be worth the benefits of its use. □

Fossil pseudo-reptiles

from Barry Cox

In Kipling's *Just So Stories*, the jaguar was dreadfully puzzled by the armadillo, for he wasn't sure whether it was a tortoise or a hedgehog. In the same way, the tiny Carboniferous tetrapods were for long a puzzle to palaeontologists, who couldn't tell whether they were amphibians or reptiles.

There was obviously no way in which their life-history could be established. It also became clear that the simple-minded assumption that any wholly terrestrial tetrapod was a reptile, while any partially aquatic tetrapod was an amphibian, wouldn't work either: there was too much ecological overlap in these early tetrapods. So palaeontologists had to look for osteological criteria on which to distinguish these animals, though their small size made this difficult—nearly all are under 30 cm long, and some are less than 10 cm long. The most reliable characteristic was found to be the structure of the vertebral centra: these seemed to have ossified in one block in the little tetrapods that were eventually called the Lepospondyls, while there were usually two pairs of ossifications in the larger forms known as Labyrinthodonts.

It eventually became clear that the lepospondyls included three distinct groups. The aquatic neotritideans had an elongate, deepened swimming tail,

and the limbless autopods looked very like the living apodans. The bulk of the lepospondyls, which lacked these specialisations, were left in the order Microsauria. Although increasing understanding of early reptile evolution made it possible to identify several small reptilian genera and remove them from the Microsauria, the order itself remained poorly defined and lacking any comprehensive, well-illustrated descriptive and analytic review. Such a review has now been provided by Robert L. Carroll and Pamela Gaskill (*Mem. Amer. phil. Soc.*, 126, 1; 1978).

Carroll and Gaskill recognise 25 genera in the order Microsauria, including five new genera. Various characters of the skull, cranio-cervical joint and scales are diagnostic of the group, but the trunk vertebrae of some are similar to those of reptiles in having small intercentra. For many years, the best-known genus was *Microbrachis*; its clear lateral-line canals and external gills, elongate body, small limbs and three-fingered manus were therefore used as the model for the restoration of other, less complete microsauro genera. However, it is now clear that *Microbrachis* is a member of a sub-order of aquatic microsaurians that were much less varied than the remainder of the group. The members of the larger sub-order, which Carroll and Gaskill call the Tuditanomorpha, show considerable variation in the size and proportions of the body, and in the dentition.

The microsaurians occupied a number of different habitats. As well as the microbrachids, some other genera seem to have lived in ponds or streams (although not in deeper water), but the short body and massive limbs of genera such as *Tuditanus* suggest that they were wholly terrestrial. Microsaurians were covered by bony scales and heavy, double-headed ribs which may have been used in costal ventilation of the lungs. There is therefore no reason to suppose that they were as ecologically restricted as the scale-less, moist-skinned amphibians of today. Microsaurians were probably carnivorous; a number of genera have rather massive teeth, and probably preyed on molluscs or arthropods that had hard shells or carapaces.

Microsaurians are known only from the Pennsylvanian (Late Carboniferous) and Early Permian. They first appear alongside the first reptiles in the Early Pennsylvanian, but the microsaurians were at that time considerably more diverse than the reptiles, suggesting

that they had originated earlier and had had more time to diversify. But the reptiles quickly became the dominant group, and the microsaurians that survived into the Permian were mainly of the heavy-toothed, elongate type that looked less like reptiles and presumably competed less with them. The geographical distribution of microsaurians, to the adjoining continents of North America and Europe, is also notable. Carroll and Gaskill think that there is no particular significance in this fact, pointing out that Carboniferous deposits laid down on land or in shallow water are rare or unknown in Gondwanaland and Asia.

The general similarity in size and mode of life of microsaurians and modern amphibians makes it difficult to be sure

whether morphological similarities between the two groups indicate relationships or merely convergence. Although the Early Permian labyrinthodont *Doleserpeton* has been suggested as a possible ancestor of modern amphibians, Carroll and Gaskill point out that its only specific similarity is its possession of pedicellate teeth. There is still so great a gap in time between the earliest members of the modern amphibian orders and any of the Palaeozoic forms that there was ample time for their evolutionary transformation from any small Palaeozoic amphibian that had not already undergone divergent specialisations such as the loss of limbs. Only new Permian or Triassic discoveries are likely to solve this problem. □

Irreversible segregation in irradiated alloys

from R. W. Cahn

THE elementary theory of atomic diffusion shows that a solid solution, even if thermodynamically stable, cannot be in a state of complete equilibrium unless the concentration of solute attains a state of flat uniformity. The elementary theory of diffusion is always wrong, because no real solid is structurally uniform. Real pieces of alloy have free surfaces and contain grain boundaries, dislocations and other defects. It is well established that solute segregates to such singularities, and the degree of segregation in equilibrium depends in particular on the solubility of the solute: relatively insoluble species segregate more intensely. The temperature is the other major variable, and a lower temperature spells more segregation. This reversible process is known as equilibrium segregation; it has been intensively studied because of its practical implications, some (by no means all) deleterious. Increased intergranular corrosion and reduced ductility in creep are examples of consequential disadvantages, sintering of 'doped' alumina powder to give a translucent, pore-free solid is an instance of beneficial use. This scientifically most intriguing as well as practically important phenomenon has recently received a worthy review by Hondros and Seah (*Int. Metals Rev.* 22, 262; 1977). Equilibrium segregation is not, however, the sole form of segregation in solid solutions.

The alternative form is non-equilibrium or irreversible segregation, and it is associated with flows of point defects, lattice vacancies in particular. Such flows result when a solid is quenched from a high temperature so that it becomes super-saturated with vacancies, or else when it is being continuously

irradiated, with the consequential creation of a steady supply of vacancies and interstitial atoms. The flow of excess point defects is absorbed at a 'sink' (such as a free surface, grain boundary or dislocation) and the defects then disappear. If, in some way, the moving defects carry solute atoms along with them, then the resultant segregation is plainly irreversible, because it is brought about by a non-equilibrium, unidirectional process—the flux of point defects.

The study of this kind of segregation has been going on for about 10 yr and reviews are beginning to appear. An early account was by Anthony, who charmingly entitled it 'Atom Currents Generated by Vacancy Winds' (in *Diffusion in Solids* (ed. Nowick & Burton) Academic Press, 1975); a more comprehensive treatment, including the more recent irradiation studies which only began when Anthony was writing his review, was presented by Harries and Marwick of Harwell at a conference on 'Residuals, Additives and Materials Properties' in May 1978 (to be published by the Metals Society, London). With the help of some very recent papers, the true complexity as well as the practical implications, for nuclear reactors, of irreversible segregation is now becoming clear, and will be outlined here.

The experimental facts are that, under irradiation, solutes (both major and minor) segregate irreversibly to or from a free surface. The experiments are usually done with ion irradiation instead of neutrons, to hasten the

process. This was discovered in 1974; a recent study is by Marwick and Piller (*Rad. Effects* **33**, 245; 1977) who found in a Ni-Mn-Si alloy that manganese concentrated in the vacancy-rich layer below the surface (the vacancy 'source') whereas silicon moved out of this layer towards the sinks; the segregation was very pronounced indeed. The same investigators (*J. Nucl. Mater.* **71**, 309; 1978) confirmed the segregation of nickel in a Fe-Ni-Cr alloy to the surface sink.

It has also been found that similar segregation takes place near the surface of the tiny voids that form in some metals and alloys, over a restricted temperature range, during irradiation. (These voids result from the fact that point defect sinks are apt to absorb interstitials slightly faster than vacancies, and so those vacancies which survive both recombination with interstitials and absorption at sinks, finish up in these minute, empty holes). This segregation process was first found in 1977 in aluminium (see account in *Nature* **262**, 671; 1977) and has now been confirmed by an exceedingly painstaking electron microprobe study at Harwell (Marwick *et al. Scripta Met.* **12**, 1014; 1978). Since the void diameter is mostly in the 100–200 nm range and the irradiation-induced segregation is confined to a layer adjacent to each void of about 100 nm thickness, the utmost resolution of a modern scanning electron microscope was required to demonstrate the segregation, and a number of possible errors had to be checked for. Nevertheless, the findings are quite unambiguous: in the Fe-Ni-Cr-Mo alloy used, the Ni/Fe and Ni/Cr ratios (these being the three major elements) are enhanced near the voids. This matches the earlier finding, that nickel is enriched near surface sinks.

These findings are by no means straightforward to interpret, because the theorist is faced by an embarrassment of alternative transport processes. The most obvious is by the formation of vacancy-solute and interstitial-solute associations; vacancies and self-interstitials in the host lattice become locked to solute atoms with variable binding energies, and the bound solutes are then dragged along with the point defect flux. The most comprehensive attempt to interpret in detail the recent findings in these terms is by Lam, Okamoto and Johnson (*J. Nucl. Mater.* **73**, 408; 1978), who improved a model they had been developing for several years. To make sense of the motion of various solutes either with the point defect flux (that is, to sinks) or against that flux (that is, to regions of peak radiation damage), they were forced to postulate very complex patterns of association; for instance, interstitial-solute associations were assumed to

differ so much in binding strength that some are readily mobile while others cannot move. There are too many adjustable parameters for comfort.

A novel alternative theory has been advanced by Marwick (*J. Phys. F: Metal Physics* **8**, 1849; 1978). Marwick concentrates attention on what he terms the 'inverse Kirkendall effect'. In the normal diffusional Kirkendall effect in a binary solid solution, found in the absence of irradiation, the vacancy flow is governed by the relative partial diffusion rates of the two constituents as they mingle with each other (that is, desegregate). The excess vacancies may form voids near the diffusion interface. Under irradiation, Marwick points out, the situation is stood on its head: a vacancy flow is imposed, and any disparity of partial diffusion rates leads to segregation of solute. The segregation process then creates a countervailing vacancy flux tending to cancel out that generated by irradiation—le Chatelier's Principle in operation. Marwick analyses the process in detail and proves that it is not at all necessary to postulate point defect-solute binding: segregation can result from the inverse Kirkendall effect alone. The faster diffusing species moves up the vacancy gradient (away from sinks) at a rate proportional to the difference between the two diffusivities; the slower diffusing species drifts to the sinks. This model makes sense of the observed enrichment of nickel, a slow diffuser, at surfaces and voids. More generally, Marwick postulates that the inverse Kirkendall effect largely governs the behaviour of concentrated alloy constituents while point defect-solute associations are likely to be the more important feature for dilute solutes.

Much interest has been expressed in the implications of irreversible segregation for void-swelling (Marwick *op. cit.*; Harries, *Nucl. Energy* **17**, 301; 1978). Structural materials and cladding in fuel assemblies for fast reactors are subject to slight but potentially dangerous swelling as voids form in those parts of the assemblies which are set at the relevant temperatures. Intensive research over the past few years has led to the use of cold-worked austenitic nickel-rich alloys (containing Fe+Ni+Cr+Si+Ti) which have excellent swelling resistance at all temperatures. It may now be possible to improve these alloys even further in the light of the new information on segregation, because it is clear (especially if the inverse Kirkendall effect is dominant) that the enrichment of slow-diffusing species, especially nickel, near incipient voids must impede further vacancy access, both because of the preponderance of a species in which vacancies move slowly and also because of the inverse vacancy flux (the balmy

vacancy wind) induced by the inverse Kirkendall effect. It seems likely that vacancy access to voids may be choked off almost completely, and some further accurate segregation tests with various solutes may point the way to even more effective anti-void measures. Minor solute elements may have a disproportionate effect if, as is quite possible, their presence has a large effect on the partial diffusivities of the major constituents and thus on the magnitude of the inverse Kirkendall effect. Future improvements may open up the way to fast reactor alloys containing less nickel than the present preferred alloy; nickel soaks up an undue number of neutrons and other alloys might be preferable from the viewpoint of neutron economy.

Another possibility is to prevent void formation altogether by using a non-crystalline alloy in which, presumably, no conventional vacancy flux can arise. Reichtin, Van der Sande and Baldo (*Scripta Met.* **12**, 639; 1978) have just reported that glassy Nb₄₀Ni₆₀ shows no void formation on heavy ion irradiation, and recommend that glasses like this be explored for use in nuclear reactors. □

A hundred years ago

IN the December part of the *Transunti* of the Royal Academy dei Lincei of Rome, Prof. Cossa gives an interesting account of his researches on the occurrence of the three metals cerium, didymium, and lanthanum. It appears that although these metals occur always in but minute quantities, yet their occurrence is far more frequent than is generally supposed, Prof. Cossa having been able to trace them even in bones and in the ashes of plants, not to speak of a number of minerals, such as certain apatites, Carrara marble, scheelite, &c. In Carrara marble Prof. Cossa found about two centigrammes of the mixed oxalates of cerium, lanthanum, and didymium in every kilogramme of marble; there were also traces of yttrium.

FURTHER experiments were made last Thursday in lighting the British Museum reading-room with the electric light. The result showed that by proper arrangement and at a comparatively moderate cost, there is good reason to believe that the end desired can be obtained. The Paris Société Générale d'Electricité have made the experiments at their own cost.

γ -Ray line astronomy

γ -Ray astronomy is a valuable source of information on solar activity, supernovae and nucleosynthesis. Cosmic γ -ray lines were first observed from solar flares and more recently from the galactic centre and a transient event. The latter may give an important insight into nuclear reactions taking place near neutron stars and black holes and a measure of the gravitational redshifts of such objects.

γ -RAY lines are the most direct probe of cosmic nuclear processes. While it has been recognised^{1,2} for two decades that nuclear γ -ray spectroscopy could provide basic information on such problems as solar activity, supernova dynamics and nucleosynthesis, only recently have positive observations of celestial γ -ray lines been made.

The first cosmic γ -ray lines were observed³ from solar flares. These lines are produced in nuclear processes on time scales of several minutes by the interaction of flare-accelerated particles with the solar atmosphere. Solar γ -ray observations have provided⁴ important information on particle acceleration mechanisms, and on the flare process itself.

The strongest observed⁵ steady celestial γ -ray line is at 0.511 MeV resulting from positron annihilation. Many mechanisms can contribute to galactic positron production, and two of these, energetic particle reactions and nucleosynthesis, also produce other detectable lines. As we shall show, the bulk of the positrons responsible for this annihilation radiation may come from processes of explosive nucleosynthesis in supernovae. Such positrons result from relatively long-lived radioisotopes whose decay is accompanied by several strong de-excitation γ -ray lines. These lines have not yet been detected, but the predicted fluxes are within the range of instrumentation planned for forthcoming γ -ray observations. The measured 0.511-MeV line intensity already places constraints on the present rate of nucleosynthesis in the Galaxy.

Cosmic γ -ray lines from a transient event have recently been observed⁶. These lines seem to result from energetic particle reactions similar to those that take place in solar flares, but not in similar environments. The identification of the lines requires a redshift of a magnitude that suggests the strong gravitational fields of compact collapsed objects. Such γ -ray line observations may probe nuclear reactions taking place in the vicinity of neutron stars and black holes, and measure the gravitational redshifts of such objects⁷.

We first discuss the flare observations and their implications. The study of γ -ray lines from flares is important not only for gaining unique insights into the flare process, but also for the development of the theory of astrophysical γ -ray line production.

Solar γ rays

Solar γ -ray lines were first observed³ from the 4 and 7 August 1972 flares with a NaI(Tl) detector on the 7th Orbiting Solar Observatory (OSO 7). For the 4 August flare, the observed lines, at 2.22, 0.51, 4.44, and 6.13 MeV, and the continuum above 1 MeV, had fluxes of 0.28, 0.06, 0.03, 0.03, and 1 photons $\text{cm}^{-2} \text{s}^{-1}$ respectively. The duration of the event was about 10^3 s. Lines at 2.22 and 0.51 MeV were also detected during the decay phase of the 7 August flare, but only upper limits could be set on the 4.44 and 6.13 MeV lines and the continuum from this flare. Observations of the 2.2-MeV line have been reported^{8,9} from the flares of 22 November 1977 and 11 July 1978.

All these lines result from nuclear interactions of flare-accelerated particles most probably in the chromosphere or lower corona. The strongest line, at 2.223 MeV, is due to neutron capture on hydrogen, $^1\text{H}(n, \gamma)^2\text{H}$. The neutrons with initial energies of 1–100 MeV, are thermalised and captured in the photosphere. The width of the 2.223-MeV line, determined by the photospheric temperature, is very narrow (~ 100 eV). Neutron capture on ^1H , however, must compete⁴ with capture on ^3He , even though ^3He is only a minor constituent of the photosphere, because the cross-section for the reaction $^3\text{He}(n, p)^3\text{H}$ is about four orders of magnitude larger than that for the reaction $^1\text{H}(n, \gamma)^2\text{H}$. Observations of the 2.223-MeV line intensity set a limit on the photospheric $^3\text{He}/^4\text{He}$ ratio of several times 10^{-4} ; this limit is comparable to the measured $^3\text{He}/^4\text{He}$ ratio in the chromosphere and solar wind (see ref. 10).

Radiative neutron capture on ^{56}Fe , which produces two strong lines at 7.632 and 7.646 MeV, is also of considerable astrophysical interest⁷. These lines should be dominant in an iron-rich medium such as the surface of a neutron star.

The second strongest line from solar flares is at 0.511 MeV from positron annihilation. The principal sources of positrons in flares are π^+ mesons, short-lived radioactive positron emitters such as ^{11}C , ^{13}N , ^{14}O and ^{15}O , and the first nuclear level of ^{16}O at 6.052 MeV which decays by electron-positron pair emission. The initial energies of the positrons range from several hundred keV to tens of MeV, but only a small fraction annihilate at these high energies. The bulk of the positrons slow down to energies comparable with those of the ambient electrons, where annihilation takes place either directly or from bound states of

Fig. 1 Calculated¹² spectrum of positron annihilation radiation in cold atomic hydrogen.

positronium. Positronium is formed by radiative combination with free electrons and by charge exchange with neutral hydrogen; 25% of the positronium annihilates from the singlet state and 75% from the triplet state.

Direct annihilation produces two 0.511-MeV photons in the positron-electron rest frame. Singlet positronium also annihilates into two such photons, but triplet positronium decays into three photons which form a continuum at energies below 0.511 MeV. This continuum, however, is significant only if the ambient density is less than about 10^{15} cm^{-3} so that triplet positronium is not broken up by collisions before it can annihilate.

If the ambient medium is almost neutral ($n_e/n_H \leq 0.05$), about 95% of the positrons form positronium in flight. If on the other hand, the medium has a higher degree of ionisation, energy loss to the plasma thermalises¹¹ the positrons before they can annihilate directly or form positronium. In this case, direct annihilation dominates if the temperature is greater than about 10^6 K , while at lower temperatures the positrons form positronium by charge exchange and radiative combination.

If the density of the ambient medium is sufficiently low ($\leq 10^{15} \text{ cm}^{-3}$), the spectrum of the annihilation radiation in a neutral medium depends on the kinetic energy of the positronium formed in flight and on the positron-neutral atom interaction leading to direct positron annihilation. This spectrum, obtained¹² from a Monte Carlo simulation, is shown in Fig. 1. The full width at half maximum (FWHM) of the 0.511-MeV line is $\sim 5 \text{ keV}$, and the asymmetry due to triplet positronium annihilation can be clearly seen.

In an ionised medium, the width of the 0.511-MeV line depends mostly on the temperature; the FWHM is about 3 keV at 10^5 K and it varies approximately as the square root of the temperature. Note that in an ionised medium the 0.511-MeV line can be substantially narrower than in a neutral medium. For example, in a partially ionised warm gas at 10^4 K (such as in a young supernova remnant) the width of the line is $\sim 1 \text{ keV}$, while in a cold neutral medium (such as an interstellar cloud) the width is $\sim 5 \text{ keV}$.

The expected width of the 0.511-MeV line from solar flares could range¹¹ from a few keV to several tens of keV depending on whether the annihilation takes place predominantly in the cool photosphere or the hot flare plasma. Because of its low energy resolution, the NaI(Tl) detector on OSO 7 has set only an upper limit ($\sim 40 \text{ keV}$), but future high resolution observations, by measuring the line width, may determine the predominant positron annihilation site.

In addition to neutron and positron production, energetic particle reactions lead to many other lines resulting from de-excitation of nuclear levels. Figure 2 shows the spectrum from

Fig. 2 Calculated¹³ nuclear de-excitation γ -ray spectrum from energetic particle reactions.

such de-excitation, calculated¹³ by a Monte Carlo simulation of an energetic particle population with spectrum proportional to E^{-2} interacting with a cold ambient medium. Here E is energy per nucleon, and both the energetic particles (at the same E) and the ambient medium are assumed to have solar composition. The narrow lines result from the de-excitation of ambient heavy nuclei excited by energetic protons and α particles, while the underlying broad component is due to de-excitation of energetic heavy nuclei interacting with ambient H and He. The strongest narrow lines, at 4.44 and 6.13 MeV, due to ^{12}C and ^{16}O de-excitation, respectively, were observed³ from the solar flare of 4 August 1972. Because the ratio of the intensities of the 4.44- and 2.223-MeV lines depends strongly on the spectrum of the energetic particles, the observed ratio provides information on this spectrum in the flare region⁴. The broad component, as well as other narrow lines which were not resolved in the 4 August 1972 observations, could account^{14,15} for all of the observed radiation above 4 MeV. Several other narrow lines could also be detected from large flares with instrumentation of higher sensitivity than that flown on OSO 7, for example, the 0.847-MeV line (Fig. 2) from ^{56}Fe and the 15.11-MeV line¹⁶ from ^{12}C .

An important result¹⁰ of solar γ -ray studies concerns the acceleration of protons, nuclei and electrons to energies greater than about 1 MeV. It seems that the mechanism for this acceleration differs from the bulk energisation of solar electrons to tens of keV where they are manifest in powerful hard X-ray emission. Acceleration to higher energies (>1 MeV), on the other hand, is probably due to a stochastic Fermi-type process which imparts $\sim 1\%$ of the flare energy to a small fraction of the ambient particles. This acceleration may be similar to galactic cosmic-ray acceleration, as several of the properties of the energetic solar particles, such as chemical composition and proton-to-electron ratio, resemble those of the cosmic rays.

Steady galactic γ -ray lines

The best observed^{5,17} nontransient galactic γ -ray line is at 0.511 MeV from the galactic centre. The observed⁵ line at 510.7 ± 0.5 keV has an intensity of 1.2×10^{-3} photons $\text{cm}^{-2} \text{s}^{-1}$ and FWHM < 3.2 keV. This observation was made in 1977 with a balloon-borne high purity Ge detector of opening angle 15° centred on the galactic centre. The line energy clearly identifies it as positron annihilation radiation; there is also some evidence for the three-photon continuum from triplet positronium annihilation.

The observed spectrum⁵ is shown in Fig. 3; the solid curve is the sum of the extrapolated low energy continuum (dashed curve) and a three-photon continuum assuming $\sim 90\%$ annihilation by positronium. This fraction is consistent with positron annihilation in a low density ($< 10^{15} \text{ cm}^{-3}$) and low temperature ($< 10^6 \text{ K}$) medium¹², and implies about 0.6 photons in the 0.511-MeV line per positron.

The 3.2-keV upper limit on the width of the 0.511-MeV line suggests¹² that the bulk of the positrons annihilate in an ionised medium ($n_e/n_H \gg 0.05$), because in cold interstellar clouds, the line width (~ 5 keV, Fig. 1) would exceed the observed upper limit. Possible sites of annihilation could be supernova remnants, H II regions at the galactic centre and the warm ionised component of the interstellar medium. Observations with higher spatial resolution could help determine the nature of source.

Turning now to the origin of the positrons, we first consider π^+ mesons produced in high energy (> 100 MeV) cosmic ray interactions in the interstellar medium. The π^+ mesons, produced in proton-proton and proton-helium interactions, decay through μ^+ mesons into positrons. An upper limit on this positron source can be set from high-energy (> 100 MeV) γ -ray observations¹⁸, as at least part of these γ rays should result from the decay of π^0 mesons which are also produced in the above interactions. From the measured π^+ and π^0 production cross

sections, we find that the observed¹⁸ flux ($\sim 3 \times 10^{-5}$ photons $\text{cm}^{-2} \text{s}^{-1}$) of > 100 MeV γ rays from a 15° cone centred on the galactic centre implies that not more than about 2% of the observed⁵ 0.511-MeV line can be from the annihilation of positrons from π^+ decay.

There is probably also a distinct low-energy (< 100 MeV) cosmic-ray component; the interstellar density of this component, however, is not known because solar modulation excludes the bulk of the low-energy particles from the inner Solar System. γ -Ray line production from these cosmic rays has been recently evaluated¹⁵ under the assumption that their local interstellar density is 1 eV cm^{-3} , and that there are substantial gradients along the line of sight towards the galactic centre in both the cosmic-ray energy density and heavy element abundances. The resultant γ -ray line emission, including the 0.511-MeV line shown in Fig. 4, is close to its maximal allowed value. If the cosmic-ray intensity were increased, X-ray line emission at ~ 6.8 keV due to charge exchange of fast Fe ions with interstellar matter would exceed the observational upper limit on this line, and if the heavy element abundances along the line of sight were increased, the absorption of X-rays would be larger than observed. The 0.511-MeV line intensity from low-energy cosmic rays, therefore, should not be larger than $\sim 7 \times 10^{-5}$ photons $\text{cm}^{-2} \text{s}^{-1} \text{ rad}^{-1}$, or also about 2% of the observed line intensity in a 15° cone around the galactic centre.

Fig. 3 Observed⁵ 0.511-MeV line and low-energy γ -ray spectrum from the galactic centre.

Low-energy cosmic-ray interactions in the interstellar medium, nevertheless, produce a rich γ -ray spectrum which includes many nuclear de-excitation lines, as can be seen in Fig. 4. Of special interest are the very narrow lines, such as that at 6.129 MeV from ^{16}O , resulting from de-excitation of nuclei in interstellar grains¹⁹. The line broadening, which in gases is caused by the recoil velocities of the excited nuclei, is greatly reduced in solids where these nuclei or their radioactive

progenitors can come to rest before de-excitation. The detection of γ -ray lines from low-energy cosmic-ray interactions in the interstellar medium with forthcoming instrumentation would not only measure the unknown interstellar density of these cosmic rays, but also provide unique information on the distribution, motion, composition and size of interstellar dust grains.

Returning to the question of the origin of the positrons, energetic particle reactions at low energies (<100 MeV) could produce positrons in discrete sources (such as in the vicinity of a massive black hole at the galactic centre⁷) without violating the constraints set by the X-ray observations¹³. If this is the case, the 0.511-MeV line should be accompanied by strong broad line emission from nuclear de-excitation, in particular the 4.44-MeV line from ^{12}C . This line may have been observed¹⁷ in 1974 with a balloon-borne NaI (TI) detector, but this measurement was not confirmed by recent observations (J. L. Matteson, personal communication) with the first High Energy Astronomical Observatory (HEAO 1). The discrepancy could be due to time variations which will be further explored with this and forthcoming satellite-borne γ -ray spectrometers.

If, however, the nuclear interaction rate is essentially constant over the positron annihilation time, then the HEAO 1 upper limit on the 4.44-MeV line intensity from the galactic centre would require that not more than about 30% of the observed 0.511-MeV line result from such energetic particle reactions. This conclusion is only weakly dependent on the assumed composition of the ambient medium and the energetic particles, since the major contributors to positron production, C, N, and O, also produce 4.44-MeV line emission by either direct excitation or spallation. The energetic particle spectrum also does not greatly affect the positron-to-4.4-MeV photon ratio¹³. Thus, some other galactic positron sources may also be required to account for the observed 0.511-MeV line.

One such source^{2,20,21} could be relatively long-lived positron-emitting radioisotopes produced by nucleosynthesis during the explosive ejection of matter in supernova explosions. The decay of these isotopes is accompanied by de-excitation γ -ray lines. The principal isotopic decay chains are shown in Table 1, together with the relevant mean lives, de-excitation line energies, and number of positrons and photons per disintegration. The isotopic yields, normalised to ^{56}Ni , are based on Solar System abundances²⁴, and on the assumption^{22,23,25} that all of the Solar System ^{56}Fe , ^{57}Fe and ^{44}Ca , and 1%, 0.5%, and 0.1% of the ^{60}Ni , ^{22}Ne and ^{26}Mg , respectively, are produced explosively through the decay chains shown in Table 1.

Even though nucleosynthesis takes place in dense regions which are opaque to γ rays, the expanding envelope can become transparent if there is sufficient delay between the synthesis of the isotopes and the emission of the photons. For the de-excitation lines, the delay is due only to the lifetime of the parent isotope. But for the 0.511-MeV line, the delay can be longer because of the finite duration of positron slowing down and annihilation. Thus, even relatively short-lived isotopes such as ^{56}Co may be important sources of positrons for annihilation radiation.

Although the lifetime of ^{56}Co may not be long enough for the supernova to become transparent to its de-excitation lines, a significant fraction of the positrons from ^{56}Co may escape from the supernova²⁰ and annihilate in regions which are transparent to the γ rays. Furthermore, even if transparency is achieved by sufficiently rapid expansion of the supernova envelope and low ejected mass, the de-excitation lines from ^{56}Co decay could only be seen for a short time (a few years) after the explosion. Therefore, these lines would be observable mostly from extragalactic supernovae from which the expected fluxes are relatively small. The slowing down and annihilation times of the positrons, however, can be longer than the interval between supernova explosions²¹, and this could lead to an essentially steady galactic emission at 0.511 MeV. The time dependences and detectability of the various other de-excitation lines listed in Table 1 have been discussed in detail elsewhere²³.

Table 1 Isotopic decay chains from nucleosynthesis in supernovae

Decay chain	Mean life (yr)	$Q/Q(^{56}\text{Ni})$	Positrons or photons per disintegration	
$^{56}\text{Ni} \rightarrow ^{56}\text{Co} \rightarrow ^{56}\text{Fe}$	0.31	1	e^+	0.2

			1.809 MeV	1

It has been estimated²⁰ that $\sim 10\%$ of the positrons from ^{56}Co decay could escape from the supernova. This escape fraction would make ^{56}Co the dominant positron source for processes of nucleosynthesis, as can be seen from Table 1. The production of $\sim 2 \times 10^{43}$ positrons s^{-1} in the Galaxy, as indicated by the 0.511-MeV line observations⁵, implies a present rate of nucleosynthesis of $\sim 10^{43}$ iron nuclei s^{-1} . This is $\sim 10\%$ of the average rate of nucleosynthesis over the age of the Galaxy, and is consistent with current models²⁶ of galactic chemical evolution. The fraction of escaping positrons from supernovae is very uncertain, however, and requires further theoretical study. If the escape fraction for ^{56}Co were much lower than 0.1, ^{22}Na decay could become the dominant positron source, as can be seen from Table 1. But the ^{22}Na yield from supernovae²⁵ is also very uncertain. ^{22}Na is also produced in novae, with a yield of about 10^{48} nuclei per nova explosion²⁷. To produce $\sim 2 \times 10^{43}$ positrons s^{-1} in the Galaxy, however, ~ 600 novae per year would be required, and this rate is higher by an order than current estimates of the galactic nova rate.

As there are other potential positron sources, a test of the explosive nucleosynthetic origin would be the detection of the associated de-excitation γ -ray lines. A good prospect is the 1.809-MeV line from ^{26}Al decay²⁸. Because of the long lifetime of this isotope, the 1.809-MeV line should be observed as steady galactic emission with an intensity of $\sim 5 \times 10^{-5}$ photons $\text{cm}^{-2} \text{s}^{-1} \text{rad}^{-1}$ from the direction of the galactic centre; the long half-life of the ^{26}Al also implies a very narrow width for this line (~ 3 keV).

Another possible positron source could be pair production in the magnetosphere of pulsars²⁹. But observations of the Crab Nebula have so far not detected line emission at 0.511 MeV from this object. Although a line at 0.400 MeV, attributed to gravitationally redshifted 0.511-MeV emission was detected³⁰ from the general direction of the Crab, this line was not seen⁶ in an earlier flight which viewed the same region. This suggests that the 0.400-MeV line from the direction of the Crab could be due to a transient event.

Transient γ -ray lines

In addition to steady γ -ray line emission exemplified by the 0.511-MeV line from the galactic centre, γ -ray lines have also been observed from transient events. γ -Ray bursts of duration up to tens of seconds are a well recognised cosmic phenomenon, but their energy spectra have not yet been measured with sufficient resolution to discern whether they contain significant line emission. There seems, however, to be another class of

γ -ray transients in which essentially all the observed radiation is in the form of lines. Such a γ -ray line transient was discovered⁶ with a balloon borne Ge(Li) detector on 10 June 1974. This event, lasting ~ 20 min was characterised by strong emission in four relatively narrow energy bands or lines with no detectable continuum. The four observed lines at energies of 0.40–0.42, 1.74–1.86, 2.18–2.26 and 5.94–5.96 MeV had average intensities of 7×10^{-3} , 3.2×10^{-2} , 1.5×10^{-2} and 1.5×10^{-2} photons $\text{cm}^{-2} \text{s}^{-1}$, respectively, during the event. These lines showed statistically significant increases in emission compared both to the intensity in the adjacent continuum and to that in the same energy bands before and after this event. A simultaneous increase was observed in the CsI(Na) shield detectors with an intensity consistent with that observed just in the lines. This transient source seems to lie within $\sim 20^\circ$ of RA 7h and dec 20° . One possible candidate for the source is the object $\gamma 195+5$ which has been observed³¹ in high-energy γ rays but not yet at other wavelengths. The Crab Nebula was also near the edge of the field of view.

There are no simple nuclear schemes that can account for all four observed lines, as there are no obvious candidate nuclei for direct emission at ~ 0.41 and 5.95 MeV. A source seems to be required⁷ which is effectively bimodal, producing both redshifted and non-redshifted lines. The observations could then be understood in terms of neutron capture and positron annihilation, which are also the strongest line producing mechanisms in solar flares. Specifically, the ~ 0.41 -MeV line could be redshifted positron annihilation radiation and the 1.79- and 5.95-MeV lines could be redshifted neutron capture on ^1H and ^{56}Fe , respectively. The required redshift Z of between 0.24 and 0.28, could arise from the gravitational field of a neutron star of mass 1.4–1.8 $M_\odot$. Episodic accretion onto such a neutron star from a close binary companion could lead to the formation of a high temperature ($>10^{10}$ K for ions) accretion disk in which

nuclear interactions could take place producing neutrons and positrons. Positron annihilation and neutron capture on iron and hydrogen at and near the surface of the neutron star would produce the observed redshifted line emission, while the same processes in the accretion disk and in the atmosphere of the companion star would produce essentially unshifted lines, of which only the 2.223-MeV line from neutron capture on hydrogen was observed. The unshifted 0.511-MeV positron annihilation line was not seen because of the large atmospheric and detector background at this energy. The double line from neutron capture on iron should be significant only in the redshifted emission from the iron-rich surface of the neutron star but not in the unshifted emission.

As mentioned above, the 0.400-MeV line observed³⁰ in May 1976 from the general direction of the Crab Nebula may also have been a γ -ray line transient as it was not detected⁶ in an earlier flight. The June 1974 and May 1976 events may in fact have the same source, as both observations included much of the same field of view; the latter event, however, was weaker by a factor of 3.

Extragalactic γ -ray lines

γ -ray lines at 4.4 and 1.6 MeV have been reported³² from the radiogalaxy Centaurus A. The 0.511-MeV line, however, which is so prominent in the spectra of solar flares and the galactic centre, was not observed from Cen A. If the γ -ray lines from Cen A are produced⁷ in quasispherical nuclear reactions in the vicinity of a massive black hole³³, then the absence of the 0.511-MeV line could be due to the large Doppler broadening in the hot accretion gas which would make the line unobservable above the continuum. γ Rays in the MeV region have also been reported³⁴ from the Seyfert galaxy MCG4151, but the energy resolution was not sufficient to resolve possible line emission.

Fig. 4. Expected¹³ γ -ray spectrum from low-energy cosmic-ray interactions in the galaxy in the general direction of the galactic centre.

Outlook

Information on many astrophysical process and sites is encoded in the γ -ray line observations reviewed here. Following these exciting discoveries, γ -ray line astronomy is now moving into an era of more systematic study, made possible by the launch of HEAO 1 and the anticipated launches of HEAO C and the Solar Maximum Mission (SMM) in the autumn of 1979. The γ -ray spectrometer on HEAO 1 is already giving results. Within a year, solar flares will be explored with the γ -ray spectrometer³⁵ on SMM, and galactic and extragalactic γ -ray lines will be studied by a high resolution spectrometer³⁶ on HEAO C. At the same time, high altitude balloon-borne spectrometers should continue to provide important results on discrete sources.

Looking further into the future, perhaps the most exciting prospect for γ -ray line astronomy will come with the launch of the Gamma Ray Observatory in 1984. This observatory is not yet an approved mission. Two of its five experiments, a Ge spectrometer and a NaI spectrometer, will observe γ -ray lines with much higher sensitivities than the instruments flown to date or planned for the immediate future. Together, these satellite and balloon-borne experiments should establish γ -ray line astronomy as a vigorous observational science.

Water–rock partition coefficients and the composition of seawater and river water

M. Whitfield & D. R. Turner

Marine Biological Association of the United Kingdom, The Laboratory, Citadel Hill, Plymouth, UK

Using a simple chemical reactor model a strong correlation is established between the mean oceanic residence time of an element and the partitioning of that element between seawater and crustal rock. The ocean–rock partition coefficient ($K_{Y(sw)}$) is shown to be related to the electrostatic contribution to the element–oxygen bond energy (Q_{YO}) and a second correlation is established between these parameters. In this way the concentrations of all the elements so far identified in seawater fall in a coherent pattern. The global mean composition of river water, which represents an intermediate step in the formation of seawater from rock weathering, is shown to conform to a similar pattern.

THE concentrations of nearly 70 elements have now been determined in seawater and, although the chemistry of seawater has been frequently reviewed^{1–3} no general rules have emerged that enable the concentrations of all the elements to be incorporated in a simple yet coherent pattern. According to one hypothesis^{4–6}, seawater has been produced by the reaction,

As there have been no major changes in the mean composition of either the igneous rocks or the sediments over the past few billion years^{4,7} the composition of seawater has probably remained fairly constant over this period—in order of magnitude terms at least. Aided by the vast flux of material through the oceans^{5,7} and by the uplift and reweathering of sedimentary rock^{7,8} (sometimes following metamorphism) the ocean–rock

system has run so close to a steady state that, for more than 60 elements the rate of input to the oceans (by river transport) is almost exactly balanced by the rate of removal (by sedimentation)⁹. As the oldest marine sediments are no more than a few hundred million years old it is possible that the same material has passed through the oceans several dozen times during the Earth's history. This suggests that it should be possible to use the partitioning of the elements between the oceans and the crustal rocks to provide further insight into the nature of seawater itself.

Before we can draw meaningful conclusions from such an exercise we must consider the reactivity of the elements in seawater because, as Forchhammer¹⁰ pointed out in 1865, "the quantity of the different elements in seawater is not proportional to the quantity of the different elements which river water pours into the sea, but inversely proportional to the facility with which elements in seawater are made insoluble by general chemical or organochemical reactions in the sea". The modern approach to Forchhammer's concept of chemical reactivity in the oceans is to define a mean oceanic residence time ($\bar{t}_Y$) (ref. 11). Elements will have a short residence time if they are readily incorporated in hydrogenous mineral phases and hence rapidly removed from the oceans. Over the 2,000 Myr period that we postulate for our steady-state ocean, the water has been stirred at close to 1,000 revs Myr⁻¹. If we approximate the behaviour of this well-stirred system by a continuously stirred tank reactor (or ocean bucket) which includes the world's estuaries we can use the notation of chemical reactor theory¹² to define $\bar{t}_Y$ so that

$$\bar{t}_Y = M_Y / \bar{m}_Y \quad (1)$$

where M_Y is the total mass of Y dissolved in the oceans^{11,13} and $\bar{m}_Y$ is the mean flux of Y through the oceans in unit time. If $\bar{t}_Y$ is less than the time (t_R) required for one stirring revolution of the reactor then $\bar{t}_Y$ can not strictly be interpreted as a residence time.

The weathering cycle and oceanic residence times

To relate mean oceanic residence times to the weathering cycle we introduce a crude model. The ocean bucket will be considered as one component in a sequence of interlinked reservoirs^{14,15} where the rate of transport of material from one reservoir to the next is directly proportional to the total amount of Y in the source reservoir. The subscripts A, B and C will represent the crustal rock, river water and oceanic reservoirs respectively. If we assume that the oceans are at a steady state with respect to the flux of dissolved components and that the composition of reservoir A remains constant, it can be shown that, for first order transfer kinetics over a period that greatly exceeds the residence time of elements in reservoir B,

$$k_C \bar{Y}_C N_C = k_B \bar{Y}_B N_B = k_A \bar{Y}_A N_A$$

so that

$$\bar{t}_Y = \bar{Y}_C N_C / k_B \bar{Y}_B N_B = \bar{Y}_C N_C / k_C \bar{Y}_C N_C = \bar{Y}_C N_C / k_A \bar{Y}_A N_A \quad (2)$$

N_X is the anhydrous mass (kg) of the reservoir X and $\bar{Y}_X$ is the global mean concentration ($\mu\text{mol per kg solids}$) of the element Y

in the reservoir X so that $M_Y = N_C \bar{Y}_C$. k_X is the first order rate constant for transfer of material from reservoir X. Taking logarithms in equation (2) we find that

$$\log \bar{t}_Y = \log K_{Y(\text{ow})} - \log (k_A N_A / N_C) \quad (3)$$

where

$$K_{Y(\text{ow})} = \bar{Y}_C / \bar{Y}_A$$

Equation (3) suggests that there should be a simple relationship between the partitioning of the elements between the oceans and the crustal rocks (resulting from the long-term recycling of the system) and the mean oceanic residence times (which reflect the reactivity of the individual elements in the oceans). Using tabulated values of $\bar{Y}_A$ (ref. 16), $\bar{Y}_B$ (corrected for recycled sea spray)^{17,18} and $\bar{Y}_C$ (ref. 13) we can calculate $\log \bar{t}_Y$ and $\log K_{Y(\text{ow})}$ and produce a plot (Fig. 1) showing a significant correlation for more than 40 elements that can be summarised by the equation

$$\log \bar{t}_Y = a_0 \log K_{Y(\text{ow})} + b_0 \quad (4)$$

a_0 does not have the expected value of unity (Table 1) but this is not surprising considering the crudity of the model. The $\bar{Y}$ -values used to characterise the reservoirs are at best only order of magnitude estimates for most of the elements and no account has been taken of the individual chemical behaviour of the various elements. Despite these limitations only three elements fall clearly outside the correlation. Nitrogen enters the oceans as nitrate but, rather than accumulating in the oceanic reservoir it is converted to gaseous nitrogen under anoxic conditions and is then lost to the atmosphere. An ocean at thermodynamic equilibrium would contain 0.1 M nitrate ion²¹. To account for the behaviour of this element and also for that of carbon, a fifth reservoir (the atmosphere) should be introduced into the model. Because of this anomalous behaviour, nitrogen was omitted from the statistical analysis of Fig. 1. For silver and antimony quite large discrepancies arise between the residence times calculated from the input of dissolved solids by the world's rivers¹⁷ and those calculated from the formation of hydrogenous sediments^{22,23}. If the sedimentation values, rather than the river input values, are plotted for these elements the points fall within the correlation limits (Fig. 1, arrowed data points). Only five elements (Fe, Al, La, Zr and Pb) have residence times that are less than t_R and these elements form a tightly grouped set in Fig. 1. From tabulated values of $\bar{Y}_A$ (ref. 16) and $\bar{Y}_C$ (ref. 13) equation (4) can be used to calculate mean oceanic residence times for elements not included in Fig. 1 that should be accurate to within an order of magnitude.

The importance of the residence time concept for estimating the response of the oceans to changes in the rate of input of material has recently been re-emphasised²⁴. Because the time span of the injection must be greater than t_R for a valid application of the residence time concept, the use of $\bar{t}_Y$ -values for predicting the effects of anthropogenic inputs over the next few centuries must be treated with caution. However, these values should be useful for discussing the stability of ocean chemistry in the geological past.

Table 1 Linear regression fitting parameters for the correlations discussed in the text ($y = ax + b$)

Fig. no.	Elements considered	n^*	y	x	a	b	$Sy, x^\dagger$	$r^\ddagger$	$r_{0.1}^\S$
1	All except N	44	$\log \bar{t}_Y$	$\log K_{Y(\text{ow})}$	0.59 ± 0.05	6.25 ± 0.16	0.77	0.88	0.52

Fig. 1 The relationship between the mean oceanic residence time ($\bar{t}_Y$) and the seawater-crustal rock partition function ($K_{Y(sw)}$) of the elements. ∇ , pre-transition metals; $\blacksquare$, transition metals; $\bullet$, B-metals; $\blacktriangle$, non-metals. Open symbols indicate $\bar{t}_Y$ -values estimated from sedimentation rates. The solid line indicates the linear regression fit (Table 1) and the dashed lines the Working-Hotelling confidence band at the 0.1% significance level¹⁹. Nitrogen was omitted from the statistical analysis for reasons given in the text. The horizontal broken line indicates the time required for one stirring revolution of the ocean (t_B). (The source data used in the preparation of Figs 1 to 4 could not be included in this paper because of space limitations but they are available in tabulated form on request from the authors.)

Relationship between composition of river water and seawater

Rather than attempting to develop a more complex model to account for the observed values of a_0 and b_0 (equation (4), Table 1) we will treat equation (4) as an empirical relationship and will focus instead on the factors controlling $K_{Y(sw)}$. Substituting $\bar{t}_Y$ from equation (2) into equation (4) we can show that

$$\log(\bar{Y}_C/\bar{Y}_B) = a_0 \log(\bar{Y}_C/\bar{Y}_A) + b'_0 \quad (5)$$

where

$$b'_0 = b_0 + \log(k_B N_B / N_C)$$

This equation is an empirical relationship independent of the multiple reservoir model. Subtracting $\log K_{Y(sw)}$ from both sides of equation (5) results in

$$\log K_{Y(rw)} = (1 - a_0) \log K_{Y(sw)} + b'_0 \quad (6)$$

where $K_{Y(rw)} = \bar{Y}_B/\bar{Y}_A$. Equation (6) suggests that river water represents an intermediate stage in the formation of seawater from the weathering of rocks, and that the partitioning of elements between the solid and aqueous phases is controlled by the same factors in each case. The controlling factor cannot generally be precipitation of simple salts (such as hydroxides, and carbonates) as solubility product calculations show that the majority of the elements in seawater have lower concentrations than the limit set by their most insoluble compounds^{22,25}. Schindler²⁶ has suggested that adsorption-desorption reactions at the surfaces of minerals which are essentially oxide-dominated matrices (mainly silicates, aluminosilicates, oxides, hydroxides and carbonates) control the concentrations of many trace metals in seawater. He has produced some convincing calculations for mean oceanic residence times on the assumption that the rate of removal of trace elements from the oceans is controlled by adsorption reactions at the surface of amorphous

silica. In this and other oxide matrices the elements attach themselves to the mineral surfaces through the deprotonated surface hydroxyl groups²⁶. This is essentially an ionic interaction, the strength of which can be related to the electronegativity of the element in question²⁷.

Electronegativity and the partitioning of elements

Pauling²⁷ suggested that the nature of the chemical bond formed between any two atoms could be related to the ability of the individual atoms to attract the electrons available for bond formation. To this end he formulated an electronegativity scale that provided a crude but effective measure of the electron attracting capabilities of the elements. The measured energy of the Y-O bond is found to exceed the arithmetic mean of the Y-Y and O-O bond energies by a quantity Q_{YO} which can be related to the electronegativities of the elements (x_Y and x_O respectively) by

$$Q_{YO} = (x_Y - x_O)^2 eV \quad (7)$$

Q_{YO} is therefore a measure of the electrostatic contribution to the Y-O bond energy and we will use Q_{YO} as a measure of the attraction that an oxide-based mineral lattice will exert on the element Y. Using tabulated electronegativity values^{16,28} we can plot $\log K_{Y(sw)}$ (Fig. 2) and $\log K_{Y(rw)}$ (Fig. 3) against Q_{YO} . In accordance with equation (6) we find that $\log K_{Y(rw)}$ and $\log K_{Y(sw)}$ show similar dependence on Q_{YO} and that $\log K_{Y(rw)}$ shows the more marked dependence. In each case there are significant linear correlations between $\log K_Y$ and Q_{YO} (Table 1) summarised by the equation,

$$\log K_Y = a_1 Q_{YO} + b_1 \quad (3)$$

The smaller number of data points and greater scatter of the river water plot (Fig. 3) reflect the greater difficulty of defining and quantifying a meaningful average for river water compared

Fig. 2 The relationship between the seawater-crustal rock partition function ($K_{Y(sw)}$) and the electrostatic contribution to the Y-O bond energy (Q_{YO} , equation (7)). Classification (Table 2): $\circ$, L1 lithophiles; $\bullet$, chalcophiles and siderophiles; $\triangle$, L2 and L3 lithophiles. The solid lines indicate the linear regression fits (Table 1) and the dashed lines the Working-Hotelling confidence band at the 0.1% significance level¹⁹. Lines cutting across the main sequence of elements break the sequence into groupings discussed in the text. The oxidation states used are those considered to be thermodynamically stable in oxygenated seawater¹³ with the exception of Cr(III) and Mn(II) as there is evidence that these metastable forms are important in seawater. Thallium has been considered as Tl(III) because recalculation of the available data shows this to be the thermodynamically favoured oxidation state.

Table 2 Solid-state classification of the elements*

Geochemical classification	Preferential occurrence	Chemical characteristics	Q_{YO} range
Siderophile (S)	Metallic phase with Fe	More noble than Fe. Weak O and S affinity	1-4
Chalcophile (C)	Sulphide phase	Strong S affinity	1-4
		Cationic (L1)	>3.5

† For halide ions $Q_{YO} < 1$.

with seawater. The anomalous positions of Ag and Sb in this plot probably arise from an overestimate of $\bar{Y}_B$ in each case particularly as the oceanic residence times of the elements calculated using river inputs are also anomalous (Fig. 1). This plot should be reconsidered when more accurate data become available for the global mean composition of river water. It should also be possible to construct analogous plots for particular fresh water systems (rivers or lakes) provided that the mean composition of the rocks in the appropriate drainage basins are used instead of $\bar{Y}_A$.

In the seawater plot (Fig. 2) we find that three groups of elements fall outside the main correlation. The elements Cl, S, B are normally considered to be 'excess volatiles'²⁹, that is they have a significant source in volcanic emissions which could result in an enhanced partition coefficient. Cd is fairly volatile (boiling point 765 °C) and may be enriched in the oceans in a similar way. In river water (Fig. 3) where the residence time is too short (<1 yr) for 'excess volatile' inputs to be significant these elements all fall on the main correlation. The other divergences from the main linear correlation are related to hydroxide solubilities. To achieve the expected value of $K_{Y(rw)}$, Fe would need to exceed its hydroxide solubility product by several orders of magnitude²¹. Iron therefore falls below the main correlation because of a combination of high abundance in crustal rock and low solubility in seawater. Although the data are more equivocal, a similar explanation probably applies to Ti and Al which are also very abundant in the Earth's crust³⁰. In river water (Fig. 3) where the lower pH and lower ionic strength make hydroxide precipitation less favourable these three elements also fall in the main correlation. The final group of anomalous elements are the Group IA and IIA metals (less beryllium). These elements differ from the rest of the electropositive elements in that they form soluble oxides and hydroxides. This arises from the relatively low charge/radius ratio of these cations, and as a result they show only a weak affinity for oxide lattices in aqueous media despite their low electronegativity. The extent to which the Group IA cations are extracted, for example, depends largely on the hydration energies that are released when the cations are incorporated into the water structure so that their $K_{Y(rw)}$ -values follow the Hoffmeister affinity sequence for ion-exchange³¹. These elements are only slowly removed from seawater so that they have long residence times (Fig. 1), and anomalously high K_Y values (Fig. 2). In river water (Fig. 3) where the timescale is much shorter the anomaly is much less marked.

The elements on the main correlation lines of Figs 2 and 3 are arranged according to their ionic affinity for oxygen, and the resulting sequence correlates well with the approximate geochemical classification of the elements first introduced by Goldschmidt³² (see Table 2). The lithophile/chalcophile division is a solid-state analogue of Ahrlund's classification of (a) and (b) cations in aqueous solutions^{33,34}: (a) cations prefer F, O, N as ligands while (b) cations prefer Cl, S, P. Both the solution and solid-state classifications show coherent groupings in the periodic table^{34,35}, but only the solid-state (geochemical) classification shows a clear correlation with the sequence of elements in Figs 2 and 3. We will redefine C, N, P, S as lithophiles as they occur as oxyanions in seawater. The litho-

philes can then be divided into three groups according to the nature of their interaction with oxygen (Table 2). The main correlation in Figs 2 and 3 has been divided into three parts. The middle portion contains virtually all the siderophiles and chalcophiles, which interact only weakly with oxygen. The ionic (L1, Table 2) lithophiles are grouped on the right of the main correlation (high Q_{YO} values) and the covalent (L3) lithophiles on the left (low Q_{YO} values). This clear correlation with the geochemical classification strongly suggests that solid-state chemistry controls the fractionation of the elements between the crustal rocks and seawater. Complexation of the elements in solution seems to be of lesser importance as the sequence of elements in Fig. 2 shows no correlation with the (a)/(b) classification of cations^{33,34}. In particular the typical (b) cations³⁴ (Ag, Au, Hg and Tl) which alone among the cations considered interact very strongly with chloride (the dominant ligand in seawater) show no anomalous behaviour. The solution chemistry of the elements is significant only where it directly affects hydroxide solubilities (Fe, Ti, Al and the Group IA and IIA metals).

The main correlation line in Fig. 2 can be used to predict $\log K_{Y(rw)}$ for the stable elements which have not yet been determined in seawater, that is Te and the platinum metals (Ru, Rh, Pd, Os, Ir, Pt). Using tabulated electronegativity values (ref. 16, p 73) we find $\log K_Y = -1.4$ for the platinum metals and -1.7

Fig. 3 The relationship between the river water-crustal rock partition function ($K_{Y(rw)}$) and the electrostatic contribution to the Y-O bond energy (Q_{YO} , equation (7)). Symbols as in Fig. 2. The solid lines indicate the linear regression fits (Table 1) and the dashed lines indicate the Working-Hotelling confidence band at the 1% significance level¹⁹. Lines cutting across the main sequence of elements break the sequence into groupings discussed in the text.

for Te. The crustal rock analyses for these elements are too scattered¹⁶ for an estimate of dissolved seawater concentration to be derived from K_Y . As expected Te (chalcophile) and the platinum metals (siderophiles) fall in the middle portion of the plot.

Weathering model revisited

We will now use a plot (Fig. 4) of the average seawater concentrations of the elements ($\bar{y}_C$, mol l⁻¹) against their average river water concentrations ($\bar{y}_B$, mol l⁻¹) to look again at the overall consequences of the weathering process. During the rapid passage through the fresh water reservoir, material is dissolved from the crustal rocks into water with a relatively low pH and ionic strength. As most of the elements are grouped within two orders of magnitude of $\log K_{Y(w)} = 0$ in Fig. 3, the composition of the solids dissolved in the fresh water reservoir bears a reasonable resemblance to that of the parent rocks. As this water runs into the ocean bucket it enters a reservoir with a much longer holding time containing water which has (after many turns of the weathering cycle) a relatively high pH and ionic strength. Here material can accumulate up to the age limit

Fig. 4 The relationship between the mean concentrations of the elements in seawater ($\bar{y}_C$, mol l⁻¹)¹³ and in river water ($\bar{y}_B$, mol l⁻¹)¹³. To convert $\log \bar{y}_N$ to $\log \bar{y}_C$ subtract 4.43 units and 1.45 units respectively for river water and seawater. The solid line follows the 1:1 correlation and the dashed lines encompass points that fall within an order of magnitude of this line. Symbols as in Fig. 2.

of the reservoir itself unless its concentration is controlled at some intermediate level by interactions with the suspended matter. The residence times of bromine and chlorine (which are concentrated to the greatest extent in the oceans relative to the rivers) are approximately equal to the age of the ocean basins themselves (Fig. 1). The elements which accumulate in the oceans (Fig. 4, elements more than an order of magnitude above the 1:1 correlation) generally show significant positive deviations from the main sequence of elements in Fig. 2 indicating

either that their concentrations are controlled by their solution chemistry rather than by their solid state chemistry (Group IA and IIA elements) or that they might have a significant auxiliary source within the oceans (Cl, S, B).

More than half of the elements are already within an order of magnitude of their final oceanic concentration (Fig. 4) before they enter the ocean bucket. The bulk of these elements fall within the main correlation bands for both seawater (Fig. 2) and river water (Fig. 3). This suggests that the controlling processes are the same in both river water and seawater and are in geological terms kinetically fast.

All the elements that show a significant depletion in the oceans relative to the river water reservoir (Fig. 4; elements more than an order of magnitude below the 1:1 correlation) have oceanic residence times that are appreciably less than the time required for a single stirring revolution of the oceans (t_R , Fig. 1). In river water all of these elements fall within the main sequence of elements (Fig. 3) suggesting that, in the initial stages at least, their concentrations are controlled by their solid-state chemistry as outlined earlier. In seawater only iron and aluminium out of this set of elements fall significantly below the main sequence of elements (Fig. 2) and their oceanic concentrations are probably controlled by the solubility of their hydroxides. The other elements (La, Pb, Zr) fall clearly within the main sequence in Fig. 2 suggesting that in the oceans, too, their concentrations are controlled by their solid-state chemistry.

The non-equilibrium behaviour of nitrogen in the oceans was mentioned in connection with Fig. 1. Comparing Figs 2 and 3 we see that in Fig. 3 (river water) nitrogen is very close to chlorine, but that in Fig. 2 nitrogen falls almost five orders of magnitude below chlorine on the $\log K_Y$ axis. If, however, we include the elemental nitrogen present in the atmosphere and dissolved in seawater (that is the nitrogen which has been lost from the ocean reservoir to the atmosphere reservoir²¹), the value of $\log K_{N(w)}$ falls only a short way below the value for $\log K_{Cl(w)}$.

Conclusions

By considering that the oceans are in a steady state with respect to the flux of weathered components from the crustal rocks and that the whole weathering cycle has been processed many times during the Earth's history, we can use the partition function $K_{Y(w)}$ to rationalise the observed composition of seawater. There is a strong correlation between $K_{Y(w)}$ and the mean oceanic residence time ($\bar{t}_Y$) as both these parameters are controlled by the ease with which the various elements are exchanged between the rocks and the aqueous phase. The ionic contribution to the Y-O bond exerts an overall control over the partitioning of the elements between the aqueous phase and the solid phase and the correlation between $\log K_{Y(w)}$ and Q_{YO} provides a rational explanation, in order of magnitude terms at least, for the seawater recipe. A similar correlation also exists for world average river water. The combination of these correlations provide a quantitative and general basis for Forchhammer's postulate¹⁰ and interrelate the concepts of reactivity and crustal abundance that have been frequently proposed as controlling factors in determining the chemistry of seawater^{13,22,36}.

Transcription and processing of cloned yeast tyrosine tRNA genes microinjected into frog oocytes

Eddy M. De Robertis

MRC Laboratory of Molecular Biology, Hills Road, Cambridge, UK

Maynard V. Olson

Department of Genetics, University of Washington, Seattle

Xenopus oocytes transcribe cloned yeast tyrosine tRNA genes and process the RNA. The processing includes base modifications, addition of the CCA end, and splicing of the intervening sequence. The primary transcript has a 5' leader extension which varies considerably in sequence and in length between different tRNA^{Tyr} loci, but is nevertheless present in all of them.

METHODOLOGICAL advances have made possible the cloning and growth in *Escherichia coli* of segments of DNA coding for various individual eukaryotic genes and these genes can be sequenced using the rapid gel methods that have greatly simplified nucleotide sequence determination. However, the function of these nucleotide sequences is not always readily apparent from the primary structure. For example, it is difficult to recognise from the DNA sequence the location of promoters and the precise start of the primary transcript. Thus there is a need for a functional assay for cloned eukaryotic genes. Here, we analyse the expression of cloned yeast tRNA^{Tyr} genes after microinjection into living *Xenopus laevis* oocytes.

Saccharomyces cerevisiae has eight unlinked tRNA^{Tyr} loci¹, each of which can be mutated into an ochre, amber or UGA suppressor^{2,3}. All eight genes code for the same mature tRNA^{Tyr} sequence. Seven of these genes have been cloned⁴ and four have been sequenced (ref. 5 and Phillipsen, Cameron and Davis, personal communication). An intervening sequence of 14 base pairs was found inserted at the 3' end of the anticodon. The sequence of the intervening sequence is also conserved between the various genes, with the exception of one base pair which has been observed to vary. However, at the flanking region at the 5' (starting) side of the tRNA sequence, the DNA sequences are almost totally dissimilar between the different genes⁵.

The intervening sequence is normally transcribed in yeast, then excised and the RNA molecule re-ligated to produce the mature tRNA^{6,7} (a process hereafter referred to as 'splicing'). This is known from the existence of a yeast temperature-sensitive mutant⁸ that accumulates a 92-nucleotide tRNA^{Tyr} precursor with the same 5' and 3' ends as the mature tRNA and

containing the intervening sequence. This work did not indicate whether this precursor represented the primary transcript, or if there is an even longer initial transcript (see below).

DNA microinjected into the nucleus of *Xenopus* oocytes is transcribed⁹ and translated¹⁰. Genes transcribed by RNA polymerase III are expressed very efficiently and with high fidelity in oocytes, as shown initially for 5S ribosomal RNA genes^{11,12} and subsequently for tRNA genes¹³⁻¹⁵. Recently, the transcription of tRNA genes from *Drosophila* and the fission yeast *Schizosaccharomyces pombe* has also been reported¹⁷ in a cell-free system derived from *Xenopus* oocytes¹⁶.

In this study we use plasmids containing yeast tRNA^{Tyr} genes for a detailed analysis of the primary transcript of a eukaryotic tRNA gene, and its processing in living cells. Our analysis was greatly facilitated by the use of genes of known nucleotide sequence, and of several members of the same gene family. We find that the initial transcript contains, in addition to the intervening sequence, an extra segment at the 5' end. This 5' leader sequence is not conserved, and varies considerably in length and nucleotide sequence between the various members of the tRNA^{Tyr} gene family. In addition, we show that many of the frog enzymes involved in tRNA production are not species specific, as they can accurately recognise yeast genes. These enzymes include RNA polymerase III, RNase P, RNA methylases, tRNA nucleotidyl transferase (CCase) and the splicing enzyme(s).

Frog oocytes transcribe yeast tRNA genes

Figure 1 shows the result of an experiment in which oocytes were injected into the nucleus with DNA of plasmid pYT-C and [α -³²P]GTP. Plasmid pTY-C (ref. 5) contains a 3-kilobase fragment of yeast DNA that includes a tRNA^{Tyr} gene and its flanking sequences cloned in the plasmid pBR 322 (ref. 18). This tRNA^{Tyr} gene corresponds to the known nonsense suppressor locus SUP 8 (M.V.O., Longhey and Hall, in preparation). Several newly synthesized RNA bands are detectable after injection of the plasmid, and their approximate lengths can be estimated using appropriate RNA markers (Fig. 1, lanes f, j). One faint band of 108 nucleotides and three main bands of 104, 92 and 78 nucleotides can be distinguished.

Thirty minutes after injection (Fig. 1, lane *b*) only the 108 and 104 nucleotide bands are detectable. The weak 108 band is always found, and although not seen very clearly in Fig. 1, is clearly visible in Fig. 4, lanes *a* and *b*, and in Fig. 5, lanes *a* and *b*. At longer incubation times the 92-nucleotide precursor is the most abundant product (Fig. 1, lanes *c*–*e*). The 78-nucleotide band co-migrates with purified yeast tyrosine tRNA (compare

Fig. 1 Autoradiogram of ^{32}P -RNAs synthesised by *Xenopus* oocytes injected into the nucleus with a plasmid containing a yeast tRNA^{Tyr} gene and cultured in saline solution for various times³⁶. Each oocyte was injected with 30 nl of a solution containing 400 $\mu\text{g ml}^{-1}$ pYT-C DNA and 10 mCi ml^{-1} [α - ^{32}P]GTP (350 Ci mmol^{-1} , Amersham). After incubation the RNA was extracted³⁷ and electrophoresed in a 7 M urea–12% polyacrylamide gel using thin (0.35 mm) spacers³⁸. About 1 oocyte worth of RNA was loaded into each slot, and the gel exposed for 2 d using an Ilford fast tungstate intensifying screen and pre-exposed Fuji Rx film³⁹. Samples *e* and *f* were run in adjacent lanes in a different 12% gel. Lane *a*, oocytes injected with pBR 322 DNA and incubated for 6 h (no yeast DNA); *b*, pYT-C injected and incubated for 30 min; *c*, pYT-C, 6 h; *d*, pYT-C, 12 h; *e*, pYT-C, 24 h. Lane *f*, purified yeast tyrosine tRNA marker¹, which was end-labelled with polynucleotide kinase and [γ - ^{32}P]ATP⁴⁰. Lane *g*, oocytes injected with pYT-C and incubated for 6 h; *h*, same as *g* but injected with 1 $\mu\text{g ml}^{-1}$ α -amanitin; *i*, same as *g* but with 100 $\mu\text{g ml}^{-1}$ α -amanitin. Lane *j*, oocytes injected with pXlo-8, a plasmid containing *Xenopus* 5S genes¹² included here as a size marker (the 5S band has 120 nucleotides, and the pre-5S one is 135 nucleotides long).

lanes *e* and *f*, Fig. 1). The proportion of the 78-nucleotide material increases with time, but is never more than the amount in the 92-precursor band (lanes *c*, *d*, *e* in Fig. 1 show 6, 12 and 24 h incubations, respectively). Even after 4 d in culture (data not shown), the 78 band represents only 30% of the RNA induced by the injection of yeast DNA. (Note, however, that oocytes transcribe the injected DNA continuously throughout this period.)

In addition to these bands, other minor products are detectable. A minor band of about 97 nucleotides is consistently observed (Fig. 1, lane *g*), and probably represents a true intermediate step in the processing of the longer initial transcript into the 92 band, as it is quite prominent after 2 h of incubation (Fig. 4, lane *a*).

Yeast tRNA^{Tyr} genes are transcribed by the oocyte RNA polymerase III, as shown by α -amanitin inhibition (Fig. 1, lanes *g*, *h*, *i*). α -Amanitin, 1 $\mu\text{g ml}^{-1}$, injected with the DNA did not significantly affect tRNA transcription. At this concentration α -amanitin abolishes RNA polymerase II transcription in oocytes injected with SV40 DNA^{10,12} or prokaryotic plasmids.¹⁹

We conclude that yeast tRNA^{Tyr} genes are transcribed in oocytes by the correct RNA polymerase (type III). We can detect a weak band 108 nucleotides long, which is then presumably processed into three main RNAs of about 104, 92 and 78 nucleotides.

Initial transcripts have a 5' leader extension

Knowledge of the DNA sequence (Fig. 2) has greatly facilitated analysis of the composition of the RNA bands; this was done using the classical RNA sequencing techniques of Sanger *et al.*^{20,21}

As the main band accumulated is about 92 nucleotides long, it seemed possible that it could be the same kind of precursor as that accumulated in the yeast mutant^{6,7}, which has the same ends as the mature tRNA but contains the intervening sequence (tRNA^{Tyr} has 78 and the intervening sequence 14 nucleotides; 78 + 14 = 92). Figure 2 shows the ribonuclease T1 oligonucleotides that can be predicted for such a molecule (this enzyme cuts RNA after G residues). Analysis of the T1 fingerprint shown in Fig. 3, left panel, confirmed that the 92-nucleotide material synthesised in oocytes contains the intervening sequence.

The spots in this GTP-labelled fingerprint were identified by elution and secondary digestion with pancreatic ribonuclease (which cuts after C and U). As the oocyte does not exchange the ^{32}P label of one injected labelled nucleotide into other nucleotides¹⁵, the spots can be recognised by the nearest neighbour to the G residue (underlined in Fig. 3, central panel). For example, the T1 oligonucleotide ApCpU $\overline{\text{G}}$ p would be cut by pancreatic ribonuclease into ApCp/U $\overline{\text{G}}$ p, giving U as the nearest neighbour to G. The identifications were confirmed by fingerprints of ATP or CTP labelled materials, in which certain spots are not labelled and others vary in intensity according to the number of labelled phosphates present. For the purposes of this study the most important spots are numbers 15 and 16, which contain the intervening sequence (and which will disappear in the 78 material), and spot 14, which contains the 5' end of the molecule.

Figure 3, right panel, shows the T1 fingerprint of the 104-nucleotide band. The oligonucleotides of this precursor are the same as for the 92 material, except that spot 14 (which was the 5' end of this RNA) no longer appears in its usual position. Two new large oligonucleotides appear (hatched tracing in centre panel, Fig. 3), and the nearest-neighbour data (Fig. 3) are consistent with their being UUAAUUG and ACUCUCG, which originate from the region of the pYT-C DNA at the 5' side of the mature tRNA.

We conclude from this that the larger precursor differs from the 92-nucleotide band at its 5' end, having a 5' leader whose sequence is consistent with that predicted from the DNA sequence of the gene.

Fig. 2 The nucleotide sequence of four tRNA^{Tyr} genes. All four genes share the same sequence between positions 1 and 92 (except for one base pair in the intervening sequence (boxed), which is CG in pYT-C and G, and TA in pYT-A and pSU4-A). The construction of these plasmids and their sequencing were described in ref. 5; all have a segment of yeast DNA cloned in plasmid pBR 322. The sequence to the left of position 1 (negative numbers) differs for the various genes, and is indicated in the upper part of the figure. The sequence of yeast tRNA^{Tyr} is indicated, as well as the sequence of the 92-nucleotide precursor RNA that accumulates in a yeast mutant^{6,7}. The predicted T1 oligonucleotides for the latter molecule are numbered in the same way as in ref. 7. pSU4-A is an ochre suppressor mutant of gene A, which was isolated from a yeast strain of different genetic background (thus explaining the nucleotide that changes on the 5' side of the start of the mature tRNA).

Fig. 3 Fingerprints of ribonuclease T1 oligonucleotides of tRNA^{Tyr} precursors synthesised by oocytes injected with pYT-C and [α -³²P]GTP. Left panel, 92-nucleotide precursor; right panel, 104-nucleotide precursor; centre panel, tracings indicating the composition of each spot, with spots numbered as in Fig. 2; the oligonucleotides that were found to be labelled after nearest-neighbour analysis (secondary digestion with pancreatic RNase) are underlined. The two new long oligonucleotides that appear in the 104 material are hatched. The 104-nucleotide material has some short oligonucleotides (paler spots on the upper part of the fingerprint) which come from the background oocyte RNA. The background of endogenous transcripts is not negligible in this case because the 104 band is relatively weak, and the fingerprint has to be exposed for longer periods. We cannot exclude the possibility that the 104 band may contain an additional short oligonucleotide, because it could be masked under one of these background spots. The RNA bands were eluted⁴⁰ from preparative gels and then digested, fingerprinted and further analysed as described by Barrell²¹. The pancreatic RNase secondary digestion products were analysed by electrophoresis in 40 cm DEAE-cellulose thin layer plates (Cel. 300 DEAE, Polygram, Macherley-Nagel) at pH 3.5 (1,000 V for 3½ h). The oligonucleotides migrate in the same way as in the usual DEAE-paper electrophoresis method²¹, but we find that thin layers are easier to handle.

Mapping the primary transcript

The primary transcript is the weak 108-nucleotide band. This was established by injecting ATP or GTP labelled in the γ -phosphate. As shown in Fig. 4, [γ - ^{32} P]ATP was incorporated only into the 108 band, whereas all other bands lack the terminal triphosphate. According to the length of this molecule, this should start at about position -19. (There is evidence that the large precursors do not have the CCA end (see below) but a short row of U residues at the 3' end of the primary transcript would have gone unnoticed in our fingerprints.) The only A residue in this region is in position -19 of pYT-C (Fig. 2), which is therefore the most likely starting place.

The presence of this 5' leader extension was confirmed by comparing the transcription of tRNA^{Tyr} genes from different loci. We mentioned earlier that the sequence of the region flanking the 5' side of the tRNA sequence varies considerably among the different yeast tRNA^{Tyr} loci. From the work described in the previous section, we now know that this region is transcribed into RNA in the initial transcripts. The plasmids pYT-C and pYT-A, for example, differ in the position of all their

A residues (except for the one at position -5) in this region (Fig. 2). Therefore, the initial transcripts of these two genes should be of different lengths, and Fig. 5 shows that this is indeed the case.

Thirty minutes after injection, pYT-C induces the 108 and 104 bands (Fig. 5, lane *a*), whereas the equivalent bands induced by pYT-A are about 5 to 6 nucleotides shorter (Fig. 5, lane *c*). Assuming that transcription starts with A or G, the most likely start for the primary transcript of pYT-A is in one of the A nucleotides in positions -12 or -11 (Fig. 2). The plasmid pSU4-A, which contains an *ochre* suppressor mutant of gene *A*, induces the same bands as pYT-A (Fig. 5, lanes *e, f*), as expected from its DNA sequence (Fig. 2). Plasmid pYT-G (Fig. 5, lanes *g, h*) produces several bands, the longest of which has about the same length (or, in some gels, slightly more) as in pYT-A and

Fig. 4 The 108 band is the primary transcript. Gel electrophoresis of the RNAs synthesised in *Xenopus* oocytes injected with pYT-C DNA and with: lane *a*, [α - ^{32} P]GTP, 2 h incubation; *b*, [α - ^{32} P]GTP, 30 min incubation; *c*, [γ - ^{32} P]GTP, 2 h incubation; *d*, [γ - ^{32} P]ATP, 2 h incubation. The position of the various precursor bands is indicated. The γ -labelled nucleotides were injected at 50 mCi ml⁻¹. The band of the primary transcript is indicated in slot *d*.

Fig. 5 The initial transcripts vary in length in different tRNA^{Tyr} loci. Gel electrophoresis of RNAs synthesised by oocytes injected with [α - ^{32} P]GTP and: lane *a*, pYT-C DNA, 30 min incubation; *b*, pYT-C, 6 h incubation; *c*, pYT-A, 30 min incubation; *d*, pYT-A, 6 h incubation; *e*, pSU4-A, 30 min incubation; *f*, pSU4-A, 6 h incubation; *g*, pYT-G, 30 min incubation; *h*, pYT-G, 6 h incubation.

Fig. 6 T1 oligonucleotides of the 92-nucleotide material (left panel) and the 78 nucleotide band (right panel) induced by the injection of pYT-C DNA into *Xenopus* oocytes. Separation was as in Fig. 3. The oocytes were labelled with [α - ^{32} P]ATP, and for this reason many of the spots present in Fig. 3 are unlabelled here. Spot 12 does not contain A but is still labelled because in the RNA its G residue has an A as nearest neighbour (sequence T $\nrightarrow$ CGA). The CCA end oligonucleotide runs very slowly in the first dimension, and was therefore run in a separate second dimension plate. Spots 15 and 16 are absent in the 78-nucleotide band, and a new spot (15 M, hatched symbols) appears.

pSU4-A. All four plasmids produce the same 92 and 78 nucleotide bands at longer incubation times (Fig. 5, lanes b, d, f, h); this is as expected, as the four genes have a very similar nucleotide sequence within this region (Fig. 2).

We conclude that the primary transcript of pYT-C starts in pppA, and that it has a 5' leader sequence most probably 19 nucleotides long. We believe this to be the first time that the transcription initiation site of an eukaryotic tRNA gene has been mapped within a region of known DNA sequence. Frog oocytes injected with DNA and γ - ^{32} P-triphosphates should be useful for identifying primary transcripts in other cloned genes.

Base modifications and the CCA end are added post-transcriptionally

Oocyte enzymes can modify at least some bases of tRNA^{Tyr} transcripts correctly. For example, of the six labelled cytosines that we examined in the nearest-neighbour analysis of the fingerprint shown in Fig. 3, left panel (92-nucleotide band labelled with GTP), only one cytosine was found to be methylated. The 5-methylcytosine was found in oligonucleotide 9 (data not shown) and corresponds to the only cytosine normally methylated in yeast tyrosine tRNA^{Tyr}^{22,23}. Other bases are probably also modified as judged from mobility changes in the fingerprints (for example, spots 4 and 11 in Fig. 3, left panel), but they were not studied in detail.

The various processing steps occur in a precise order. For example, oligonucleotide 9 is completely modified by the 92-precursor stage, but it is not modified in the 104 band. As seen in Fig. 3, spot 9 (AUCG) is displaced in the 104 fingerprint, where it co-migrates (confirmed by nearest-neighbour analysis) with spot 10 (ACUG). This is expected if spot 9 is not modified, because oligonucleotides 9 and 10 have the same length and base composition (one of each of the four nucleotides), and therefore the two spots should not be resolved by the fingerprinting technique in their unmodified form. (In yeast tRNA^{Tyr} oligonucleotide 9 is modified into AD $\overline{C}$ G; and the dihydrouridine is the modification most likely to produce such a displacement in the fingerprint.)

The CCA 3' end of the tRNA^{Tyr} is not encoded in the DNA, but is added post-transcriptionally by a tRNA nucleotidyl transferase (CCase). A spot corresponding to the oligonucleotide ApCpCpAOH was found in ATP (Fig. 6) and CTP labelled

fingerprints of the 78 and 92 nucleotide species, but not in GTP-labelled ones. The sequence of this spot was confirmed by nearest-neighbour analysis after pancreatic ribonuclease digestion (C with [α - ^{32} P]ATP and AC with [α - ^{32} P]CTP). A nucleotidyl transferase activity capable of adding a terminal A residue to tRNA and viral RNAs has been previously described in injected oocytes^{24,25}. The CCA end is present in the 92 and 78 nucleotide bands, but is absent from the 104 precursor (data not shown).

The intervening sequence is excised and the molecule re-ligated

The final product of the *Xenopus* oocyte processing seems to be a covalently intact 78-nucleotide species that does not contain the intervening sequence. Our data do not unequivocally demonstrate that the *Xenopus* splicing enzymes make the identical splice that occurs in yeast, but the splicing point can be located at or within two or three nucleotides of the correct site.

The 78 and 92 nucleotide bands differ only in the region of the intervening sequence. Figure 6 shows that T1 oligonucleotides 15 and 16 (which contain the intervening sequence) are absent in the 78 material, whereas all the other spots are conserved (this is known for GTP, ATP and CTP labelled fingerprints). In addition, a new spot appears in the tRNA-size material (15M in Fig. 6). In yeast, the splicing of the intervening sequence normally involves:

As in yeast, spot 15M made in oocytes is a larger derivative of oligonucleotide 15. This was identified by nearest-neighbour analysis of spot 15M which gave U using α GTP, and AAAU using α CTP. (There is also a second spot, much less intense, which appears reproducibly in the 78 material and is indicated as 15M' in Fig. 6; this minor component is probably also derived

Fig. 7 Main processing stages in the expression of *Saccharomyces cerevisiae* tyrosine tRNA gene C. The primary transcript has a 5' leader sequence 19 nucleotides long, and an intervening sequence 14 nucleotides long. The 5' leader segment differs in length and composition in transcripts of different tRNA^{Tyr} genes. The 5' leader is removed in at least two steps and the molecule is converted into a 92-nucleotide precursor that has been previously identified in yeast^{6,7}. The 92-nucleotide molecule contains several base modifications (not shown here) and the CCA end that is added post-transcriptionally. The intervening sequence is then excised and the molecule re-ligated to produce mature tRNA^{Tyr} (shown here with the base modifications that occur in yeast^{22,23}). The position of the anticodon in the various precursors is underlined. The secondary structure shown here for the 92-nucleotide precursor is the one preferred in ref. 7.

from spot 15, because its nearest neighbour to G is U.) Spot 15M from oocytes, however, moves more slowly in the first dimension than does its yeast counterpart⁷. This mobility difference could be due to a difference in base modification (oligonucleotide 15M from yeast contains an isopentenyl adenosine). However, we cannot rule out the alternative explanation that oligonucleotide 15M has an anomalous mobility because the *Xenopus* processing system splices the yeast precursor incorrectly, although this is unlikely. The splicing site must not lie within oligonucleotide 10 because this spot is found in α -CTP and α -GTP labelled fingerprints of the 78-nucleotide material (data not shown). The nearest-neighbour analysis of spot 15M requires that this oligonucleotide contains the sequence AAAUC, and UG in its 3' end. These data, nonetheless, do not exclude the possibility of a splice giving an oligonucleotide 15M at least 3 nucleotides longer than in yeast (for example, UAAUAAUCUUG). We consider this possibility unlikely in view of the co-migration of the mature yeast tRNA^{Tyr} and the oocyte product in polyacrylamide gels (Fig. 1).

After the intervening sequence is excised, the molecule is re-ligated. This is known because the 78 band maintains the same mobility after heating the RNA at 95 °C for 3 min in 2 volumes of formamide before loading directly on an acrylamide-7 M urea gel. In these denaturing conditions²⁶ this band would have migrated as two half-molecules if not covalently closed. Splicing of yeast tRNAs by *Xenopus* cells has also been found for the tryptophan tRNA genes using *in vitro* nuclear extracts (Ogden, Beckmann, Abelson, Söll and Schmidt, manuscript in preparation).

Conclusions and prospects

Figure 7 outlines the sequence of processing steps for yeast tRNA^{Tyr} that we have inferred from the analysis of the major RNAs that accumulate in oocytes in response to the injection of DNA from the plasmid pYT-C. Rigorous demonstration of precursor-product relationships by means of pulse-chase experiments is not feasible in this experimental system, but the time course with which the different RNA species accumulate is consistent with the view that mature tRNA^{Tyr} is formed by an orderly series of steps in which the RNAs represented in Fig. 7 are sequentially formed. In this interpretation, the 5' leader is

removed in at least two stages, resulting in a molecule with the same 5' end as the mature tRNA, but still containing the intervening sequence. Several base modifications and the addition of the CCA end are detectable for the first time at this stage. This 92-nucleotide precursor has been identified *in vivo* in a yeast mutant^{6,7}, but none of the larger RNAs has been previously described. Yeast therefore has tRNA precursors with 5' leader extensions similar to those described in bacteria²⁷.

The possible significance of the 5' leader sequence is intriguing. This transcribed region not only varies considerably in nucleotide sequence⁵ between the different tRNA^{Tyr} loci, but also in length (Fig. 5). However, all four tRNA^{Tyr} genes examined so far have a 5' leader sequence. One is then left with the question of why these segments of RNA with no obvious sequence or length constraints are always present, and not eliminated altogether. Although this cannot be answered, one possibility is that they introduce order in the intricate processing that the primary transcript must undergo before becoming tRNA, that is, some modifications could occur while the 5' leader is still present, but others cannot occur until this segment is removed.

The final major processing step—the removal of the intervening sequence and re-ligation of the RNA—is not as efficient (30% maximum) in *Xenopus* oocytes as in wild-type yeast cells⁸, but in some ways it is remarkable that it is conserved at all in such a highly heterologous system. Clearly, the enzymes involved can tolerate extensive changes in primary sequence, as the yeast and *Xenopus* tRNA^{Tyr} genes have diverged markedly (S. Clarkson and F. Müller, personal communication).

The specificity with which *Xenopus* RNA polymerase III recognises these transcriptional units is particularly surprising in view of the major biochemical differences that have been observed between the yeast enzyme and those from higher eukaryotes. The yeast enzyme differs from vertebrate RNA polymerase III in both its α -amanitin insensitivity²⁸⁻³⁰ and subunit composition³¹. We have no direct evidence that the *Xenopus* enzyme initiates transcription at the same site as in yeast. The demonstration of transcription initiation in the immediate proximity of the tRNA coding sequence strongly suggests, however, that the *Xenopus* enzyme is correctly recognising the true yeast transcription unit. For example, the plasmid

pYT-C contains 7 kilobases of DNA, but the only discrete transcripts originate from the tRNA^{Tyr} gene region, which represents <2% of the plasmid. This also applies to the other plasmids used in this study. Our results suggest that although *Xenopus* and yeast polymerase III differ in their biochemical properties, they still recognise the same initiation signals in DNA.

More extensive DNA sequencing will be required in the region preceding the transcription initiation sites within the different tRNA^{Tyr} genes before any conclusions can be drawn about the nature of polymerase III 'promoter' sequences³². The yeast tRNA^{Tyr} gene system has the major advantage that it should be possible to identify base pairs essential to the initiation of transcription by obtaining mutants that affect this process. All eight yeast tRNA^{Tyr} genes correspond to known nonsense suppressor loci^{2,3} and the set of cloned restriction fragments that contain these genes has been cross-correlated with the set of genetic loci (M.V.O., Longhey and Hall, in preparation). Methods are also well established for obtaining second-site mutations within these genes by starting with a functional suppressor and selecting for the loss of suppression^{33,34}. The system described here should provide an effective technique for

screening mutant genes for defects in transcription and in the different processing steps.

The finding that *Xenopus* enzymes can carry out several key steps in the processing of yeast tRNA^{Tyr} transcripts supports the view that yeast suppressor genes might provide nonsense suppressors if introduced into the cells of higher organisms³⁵. However, we do not yet know whether a fully functional gene product is synthesised.

We hope that in the future some of the prospects outlined above might be achieved. In the meantime, however, it is already clear that very precise information about cloned genes and their primary transcripts can now be obtained using the most crude (but most physiological) assay system of all—their expression in an intact living cell.

We thank B. G. Barrell and F. E. Baralle for advice on RNA sequencing, S. G. Clarkson, J. Abelson, and D. Söll for unpublished information, B. D. Hall, J. B. Gurdon and J. D. Smith for discussions, P. Black for technical assistance, and B. Rodbard for help with the illustrations. M.V.O. is a NIH postdoctoral fellow (grant G.M. 11895). All the recombinant plasmids used in this work were grown in Seattle in P2-EK1 containment conditions.

Angular dimensions of accreting young stars

ALTHOUGH every star passes through a pre-main sequence stage during its formation, only a few astronomical objects have been considered as likely candidates for the early protostellar evolutionary stage¹. The bulk of the energy observed as radiation emitted by a compact source in the near IR, from 2 to 10 μm , is attributed to thermal emission from a dust shell, where the opacity is a rapidly varying function of the wavelength. To study radiative transfer models, the knowledge of the spatial intensity distribution on the object surface in the near IR is crucial. We have developed a method of IR speckle interferometry² which allows the spatial spectrum of an object in a given direction in the modulus sense to be determined up to the frequency cut-off of the telescope. As usual in speckle interferometry techniques the phase is lost unless sophisticated phase-restoration techniques are used. We applied this method

to several protostellar candidates: the BN object, W3IRS5, R MonIRS3, CRL2591 and S140IR at wavelengths 4.8 and 3.5 μm . We present here the results of dealing with BN and W3IRS5, and a more detailed interpretation of the whole set will be given elsewhere.

The specklograph has the following configuration²: the image is formed at the Coudé focus ($f/181$) of the Mayall 3.81-m telescope from Kitt Peak National Observatory. A scanning mirror driven by a saw-tooth wave generator displaces this image on a slit: the motion is perpendicular to the slit and linear with time. The slit is of the order of the seeing disk size, and its width smaller than the Airy radius. The flux is collected through a cold filter ($\lambda = 4.8$ or 3.45 μm ; see Table 1) onto an InSb detector. Alternate scans were made on the object and on adjacent sky to measure in similar conditions the object power and the system- and sky-noise power. One-dimensional power spectra of the source were obtained through the following process: (1) the power spectrum of the source and of the noise were averaged over a given integration time T_0 amounting to N_B

Fig. 1 The atmosphere and telescope normalized MTF, $\langle |S(f)|^2 \rangle / \langle |S(0)|^2 \rangle$ as measured at $4.8 \mu\text{m}$ on a point source (μGem). The observations (●) are compared to the best available model of atmospheric MTF (log normal model). The telescope MTF is the theoretical diffraction limited pupil. The resulting MTF is given by the dashed line, and the best fit with the data is obtained for $r_0(4.8 \mu\text{m}) = 78 \text{ cm}$.

scans with individual duration τ ; (2) the noise power spectrum was subtracted from the source power spectrum; (3) the resulting spectrum was divided by the atmosphere plus telescope modulation transfer function (MTF), in the modulus sense.

The latter MTF is obtained on a bright point-like star, the observation of which is alternated with the observation of the object. Figure 1 shows a typical MTF including the atmosphere and the telescope transfer functions, as determined on a point source star (μGem). A more detailed analysis of the MTF properties is given in refs 2, 3. We obtain the power spectrum data points from

$$\langle |S(f)|^2 \rangle = \langle |I_A(f)|^2 - |b_A(f)|^2 \rangle_{\text{reference star}}$$

This process is summarised by

$$\text{estimation of } |o_A(f)|^2 = \frac{\langle |I_A(f)|^2 - |b_A(f)|^2 \rangle_{\text{object}}}{\langle |I_A(f)|^2 - |b_A(f)|^2 \rangle_{\text{reference star}}}$$

for $f \leq f_c$ with $f_c = D/\lambda$ the frequency cut-off of the telescope. $|o_A(f)|^2$ is a cross-section of the object two-dimensional power spectrum in the scan direction, versus spatial frequency f . $I_A(f)$ and $b_A(f)$ are respectively source and noise spectra. Averaging is made over the observation time. The estimated $|o_A(f)|$ is an average over the band pass $\Delta\lambda$.

A phase-demodulation synchronised with the scan provided a real-time detection of the object and allowed fine guiding to an accuracy well within the dimensions of the seeing disk.

Fluctuations of the wave front coherence length, that is, the Fried parameter, r_0 , with time, limit the above restoration process at least in the current experimental set-up. Most of the data presented here were obtained in stable observing conditions, where this latter effect is small or negligible. Table 1 gives

the observing parameters for the two sources discussed below. Figs 2–4 present the quantity $|o_A(f)|/|o_A(0)|$ as determined by the reduction process for either source, versus spatial frequency in the direction ϕ_0 . Error bars represent one standard deviation determined from the signal-to-noise ratio on individual scans and the number of scans N_B .

Both sources present a low frequency peak which at $4.8 \mu\text{m}$ is more conspicuous on BN than on W3IRS5. The fraction of the total source power in this peak is small: biasing effects in the reduction process⁴ do produce such peaks but we have corrected the spectra for this effect². We will, however, only assign it tentatively to an extended component within the BN object and refrain from discussing at length its possible significance.

At the time of observation the $4.8 \mu\text{m}$ spectra were degraded by spurious 60 Hz system noise beyond $f \approx 2 \text{ arc s}^{-1}$. This was not the case for the $3.45 \mu\text{m}$ spectrum on Fig. 4, which shows a very good signal-to-noise ratio up to $0.95 f_c$. This particular spectrum illustrates well the capability of the speckle method to fully exploit the MTF of a large telescope. The oscillations appearing at high frequency in Fig. 4 are expected as the process (3) above divides noise by noise for $f \gg f_c$.

W3IRS5: this source is clearly resolved. We fit the spectrum with a function

$$\left| \frac{2J_1(\pi\alpha_0 f)}{\pi\alpha_0 f} \right|$$

corresponding to a source of uniform brightness with a diameter α_0 and find $\alpha_0 = 0.28 \pm 0.08 \text{ arc s}$. This large error bar is due to rather poor atmospheric conditions during this observation and is determined from the comparison of independent spectra. If the source had radial symmetry its radial profile $O(\alpha)$ would be completely restored.

If there is any flattening the configuration is less determined and would need scans at various angles ϕ . The above angular value α_0 refers only to the direction ϕ_0 .

A single size measurement for W3IRS5 is quoted by Werner *et al.*¹ to be 3,000 AU, or 1.08 arc s . As they gave no wavelength no comparison was possible.

Wynn-Williams *et al.*⁵ derive a 350 K black body energy curve between 2 and $5 \mu\text{m}$, which corresponds to a diameter of 0.2 arc s , in agreement with our measurement in the absence of flattening. Aitken and Jones⁶ have computed the extinction to the central object from the depth of the silicate feature and derive a corrected 600 K spectrum, to which corresponds a diameter of 0.24 arc s .

Bedijn *et al.*⁷ quoted an unpublished evidence for a double source in this object, for which we find no obvious evidence. Unfortunately, this result prevents them computing a model for W3IRS5. A less elaborate model is made by Finn and Simon⁸ which fits W3IRS5 spectrum with a central cold object having a black body temperature of 375 K. The corresponding $4.8 \mu\text{m}$ diameter is 0.33 arc s , which again agrees with the present measurement.

BN object: The $4.8 \mu\text{m}$ spectrum for the BN object is significantly different from the W3IRS5 spectrum. The central peak is slightly wider but again its power is a small fraction of the total. The main difference lies in the compact source which

Table 1 Observational parameters

Wavelength (μm)	Object	Date (1978)	Magnitude m_λ	Flux (Jy)	T_0 (S)	Scan angle* (ϕ_0)	Reference star	$r_0^\dagger$ (cm)
4.78 μm	W3IRS5	Sept 11	0.8	80	552	150°	β Peg	110
$\Delta\lambda = 0.21 \mu\text{m}$	BN	Sept 11	-0.1	190	312	40°	μ Gem	240
(L)								
3.45 μm	BN	Sept 10	2.2	40	61	40°	μ Gem	165
$\Delta\lambda = 0.57 \mu\text{m}$								

Scan duration is $\tau = 38.4 \text{ ms}$.

* ϕ_0 is the angle between the scan direction and north, counted counterclockwise.

† r_0 is estimated using the low-frequency Korff asymptotic expression for the atmospheric MTF.

Fig. 2 W3IRS5 power spectrum $|O_\lambda(f)|/|O_\lambda(0)|$ versus spatial frequency in the direction $\phi_0 = 150^\circ$. Total observation time $T_0 = 552$ s. The full curve is the spectrum of a disk with uniform brightness and diameter $\alpha_0 = 0.28$ arc s. $\lambda = 4.8$ μ m. FWHM is the frequency resolution.

seems barely resolved in this particular direction ϕ_0 . The diameter of a source of uniform brightness as above would be $\alpha_0(4.8 \mu\text{m}) \leq 0.1$ arc s if we assume the measured spectrum to depart from the spectrum of an unresolved source by less than 5% on the explored frequency range.

The central peak is fitted with a gaussian component corresponding to an extended gaussian emission with FWHM 1.5 arc s.

The 3.45 μ m BN spectrum is easier to interpret. The central peak is present but is very dim and broader. It would again correspond to an extended emission with a gaussian intensity

Fig. 3 BN power spectrum $|O_\lambda(f)|/|O_\lambda(0)|$ versus spatial frequency in the direction $\phi_0 = 40^\circ$. Total observation time $T_0 = 312$ s. The full curve is the spectrum of a disk with uniform brightness and diameter $\alpha_0 = 0.1$ arc s. $\lambda = 4.8$ μ m.

profile and a FWHM of 0.9 arc s. The decrease of $|O_\lambda(f)|$ towards high frequencies is noticeable: Fig. 4 shows the spectrum of a disk having a uniform brightness and a diameter $\alpha_0(3.5 \mu\text{m}) = 0.1$ arc s. The telescope resolution in the Rayleigh criterion sense is given by $1.22 \lambda/D = 0.23$ arc s: the measured diameter is below this limit, because the high signal-to-noise ratio in the spectrum allows us to determine where it departs from being a point source spectrum.

Low⁹ has observed BN with spatial interferometry techniques and presents it as "unresolved" but does not specify the observation angle nor the wavelength nor the upper limit of the diameter. Becklin *et al.*¹⁰ fit the observed spectral distribution with a 530 K black body curve corresponding to a 0.1 arc s diameter at 4.8 μ m. This agrees with our data if there is no flattening.

Fig. 4 BN power spectrum $|O_\lambda(f)|/|O_\lambda(0)|$ versus spatial frequency in the direction $\phi_0 = 40^\circ$. Total observation time $T_0 = 61$ s. The full curve is the spectrum of a disk with uniform brightness and diameter $\alpha_0 = 0.1$ arc s. The vertical dotted line at $f = 0.95 f_c$ sets the estimated confidence limit for the restoration process. $\lambda = 3.45$ μ m.

A more elaborate treatment is given by Bedijn *et al.*⁷ who built a series of models for accreting stars. Applying these models to BN, these authors considered four possible cases, where a satisfactory fit of the observed spectrum was obtained, with a mass ratio of three between silicates and graphite grains.

The predicted 5- μ m diameter—90% of the energy within it—varies from 0.42 to 0.12 arc s. The two first models are eliminated for dynamical reasons, our data only comply with the latter one. It corresponds to the lowest luminosity $2.9 \times 10^3 L_\odot$ for the embedded object, to a foreground extinction $A_V = 12.3$, and to a spectral type B3. The large model uncertainty on the luminosity—a factor six—is greatly reduced by measurement of the angular diameter.

As Bedijn *et al.*⁷ do not give the wavelength dependence of the size for $\lambda < 5$ μ m, it is difficult to compare the 3.5 μ m data. Nevertheless, one expects the diameter of the halo, if real, to slightly decrease, as observed, owing to the contribution of inner

Table 2 Measured angular diameter (in direction ϕ_0)

	Wavelength (μ m)	ϕ_0	Extended* halo envelope (FWHM, arc s)	Central source diameter (uniform disk) arc s
W3IRS-5	4.8	150°	1.5	0.28 $\pm$ 0.08
			Very weak	
	4.8	40°	1.5	$\leq$ 0.10
BN	3.45	40°	0.9	0.10
			Very weak	

*Interpret with caution.

layers at a higher temperature and Yorke (personal communication) predicts the existence of a halo surrounding the central object for $\lambda > 2.5 \mu\text{m}$. More elaborate models are now needed, especially to compare the wavelength—and radial—dependence of the emerging intensity in the region of possible accretion.

These measurements confirm that two likely candidates for pre-main-sequence objects in the solar neighbourhood are high luminosity sources embedded in a very compact heated shell. Following Bedijn *et al.*⁷ it is unlikely that such a phase can be sustained for longer than 10^5 yr. Other evidence for a transient expansion phenomenon around the BN object was recently pointed out by Hall *et al.*¹¹ in the discovery of an expanding shell observed in the lines of the CO molecule.

Although these first measurements are restricted to a single radial direction, and do not yet answer the crucial question of the flattening in the accretion disk and its possible rotation, the method proves that sizes of the order of 40 AU are within reach in the thermal IR: radiative transfer problems and inner dynamics of accretion cores can therefore be studied observationally.

We thank Dr R. Joyce and W. Brown for technical assistance. The Kitt Peak National Observatory is operated by the Association of Universities for Research in Astronomy, Inc., under contract with the NSF.

Quasi-biennial variation of the solar neutrino flux and solar activity

THE observed flux of the solar neutrinos is lower by a factor of five than that theoretically estimated from the study of the standard model of the solar interior¹. To explain this discrepancy various theories have been proposed which disregard some of the assumptions inherent in this model. However, no theory has been able to reduce the theoretical fluxes to the observed ones^{2,3}. The experimental data obtained by Davis *et al.*¹ indicate that this discrepancy is real, so that these data should be seriously considered in any future research on the solar neutrinos. They have published these data for each period that they have observed since 1968, (Fig. 1)^{4,5}. We have used their data on the solar neutrino fluxes since 1968 to study whether the neutrino flux has any tendency to vary periodically during the solar cycle of 11 yr. The dependence of the neutrino flux on the solar activity, namely, the phase of the solar cycle, was suggested by Sheldon⁶. He explained that, in the late 1960s, the neutrino production rate in the solar core seemed to be dependent on the degree of the solar activity, as he could only refer to the early results on the neutrino flux observations. It is

Fig. 1 The observed fluxes of the solar neutrinos for the years 1970–76 (Davis *et al.* 1976).

shown here that this idea is not supported by the data on the neutrino flux obtained since 1968.

The neutrino flux may have been varying quasi-biennially throughout the solar cycle since 1968 (ref. 7), and this flux variation seems to be independent of the mean trend of the variation of the solar activity for 11 yr. Therefore, this 'quasi-biennial' variation of the neutrino flux must be related to some feature of the solar phenomena, because such a variation with a period as short as 2 yr, may produce some phenomena on the solar photosphere which are causally connected with those taking place in the interior of the Sun. One of these must be the variation of the relative sunspot numbers because they are

Fig. 2 a, The monthly mean values of the relative sunspot numbers for the years 1970–76. The moving average for 5 months is indicated by the dashed line. The mean trend of the variation of the sunspot numbers is shown by the solid line; b, The deviation of the relative sunspot numbers from the mean trend shown in (a).

Fig. 3 The relationship between the variation of the solar neutrino flux and the deviation of the solar activity from the mean trend for the years 1970–76. The open circles indicate the mean observed fluxes of the solar neutrinos shown in Fig. 1. The dashed lines give those fluxes shifted earlier by 4 months.

produced by some instability associated with hydromagnetic convective motion beneath the photosphere.

According to the power spectral analyses by Shapiro *et al.*⁸, the relative sunspot numbers vary with a period of 25.7 months. Compared with the result shown in Fig. 1, it turns out that this period is very similar to that for the quasi-biennial variation of the solar neutrino flux.

To determine whether a quasi-biennial variation for the relative sunspot numbers exists between 1970 and 1976, the moving average for 5 months was first obtained for the monthly mean relative sunspot numbers as shown in Fig. 2a. This shows that the relative sunspot numbers deduced from this average have a clear tendency to vary quasi-biennially while superimposing the mean trend, shown by the thick line, which represents the pattern for the 11-yr variation of these sunspot numbers. From the result shown in Fig. 2a, the deviation of these numbers from this mean trend can be evaluated by subtracting the numbers for the mean trend from the observed sunspot numbers averaged over 5 months with respect to each month.

The relative sunspot numbers deviation from the mean trend is shown in Fig. 2b. This shows that these numbers vary quasi-biennially, although the data for 1976 do not show such tendency clearly because this year was at the solar activity minimum. The time-series analytical method has then been applied to estimate the length of an apparent period for this quasi-biennial variation as shown in Fig. 2b. The result clearly indicates that the relative sunspot numbers for these years also vary with a period of 25.3 months, which is almost the same as obtained for other years⁸. This suggests that the solar activity always varies with a period of about 25 months, which is independent of the phase of the solar activity cycle. Furthermore, the geomagnetic disturbances are controlled by the quasi-biennial variation of the solar activity⁹.

Comparing the result of Fig. 2b with the observed data on the neutrino flux shown in Fig. 1, it follows that when the deviation is positive the observed flux of the solar neutrinos seems to be generally very high and vice versa, if we neglect small time difference.

To examine this relationship quantitatively, the observed fluxes of the solar neutrinos have been superimposed on the result shown in Fig. 2b. The result is shown in Fig. 3, where the open circles are the observed values of the solar neutrino fluxes, which are connected with the solid lines, although the error bars have been omitted. The filled circles connected with the chain lines indicate the observed fluxes shifted earlier by 4 months, for which the error bars are added to show a correlation between these fluxes and the deviation of the relative sunspot numbers. Figure 3 shows that although the statistical variation of the solar

neutrino fluxes is quite large, these fluxes, except for those of 1976, vary in phase with the variation of the sunspot numbers deviated from their mean trend. This result is, however, unexpected when we use the standard model of the Sun to investigate the production process of the solar neutrinos. This result suggests that this process is causally related to some unknown process taking place in the interior of the Sun, which must also be responsible for the quasi-biennial variation of the solar activity. As the cause of the solar activity is associated with large-scale internal motion associated with some unstable convective modes, this process may be accompanied by some form of the motion. Furthermore, the result shown here suggests that this motion can penetrate into the region where the thermonuclear fusion is taking place and thus disturb the stable burning processes of its hydrogen and the helium-3. No theory on such a motion has yet been proposed but our result means that further investigation is needed on the large-scale internal motion of the Sun, which causally connects the fusion processes with the quasi-biennial variation of the solar activity.

The standard model does not provide any means to investigate such convective motion penetrable to the nuclear-burning central core of the Sun. However, some oscillatory modes of motions may exist with longer periods not previously observed. One of these may vary with a period of about 2 yr if the quasi-biennial variation of the relative sunspot numbers has to be produced from some modes of the convective motion beneath the solar photosphere. Thus the continued observation of the solar neutrino flux for several solar cycles would give us an important clue when examining the accuracy of the standard model and its limitations in investigating the interior of the Sun in relation to the nuclear-burning processes.

There is evidence, in fact, that the azimuthal component of the convective motion, measured as the angular velocity, seems to be varying quasi-biennially during the last solar cycle no. 20 (1965–76) (ref. 7). This motion, therefore, seems to be associated with the convective motion mentioned above. However, such motion can never be derived from the study of the standard model of the Sun.

These results indicate that the production rate of the neutrinos in the solar interior varies quasi-biennially and may be causally associated with the convective motions responsible for the quasi-biennial variation of the relative sunspot numbers.

Tensile strength of water

THE measured tensile strength of water has long been known to be significantly less than theoretical predictions and the reduced strength is normally attributed to the presence of solid impurities that serve as nucleation sites for rupture of the liquid¹. A favourite method of measuring tensile strength is through the dynamic stressing of a liquid by an acoustic field. At sufficiently large values of the peak negative acoustic-pressure amplitude the liquid ruptures and forms a rapidly growing vapour cavity that collapses violently during the positive portion of the cycle. This cavity collapse is normally violent enough to be observed easily with the unaided eye or ear. Such an event is termed the acoustic cavitation threshold and is a measure of the tensile strength of a liquid. Although some successes have been obtained in achieving measured values of the tensile strength comparable to theoretical predictions for extremely small samples² or after extensive filtration³, I know of no current theory for the prediction of values of the dynamic tensile strength for ordinary distilled water. Using a modified version of a recent theory by Apfel⁴, an equation is presented here that correctly predicts the variation of the acoustic cavitation threshold of water with surface tension, dissolved gas content and temperature.

It is assumed that there exists in the body of the liquid numerous nonpolar solid impurities that contain cracks and crevices in which gas pockets may be stabilised against dissolution. Scanning electron micrographs have been made of filtered solid impurities and show innumerable sites for possible gas-pocket stabilisation⁵. Figure 1a is a typical micrograph of a filtered particle. Following a theory of Apfel⁴, and others^{1,6}, it is possible to determine requirements on the threshold acoustic pressure required to nucleate a free gas bubble that will serve as a preferential site for liquid rupture. Apfel⁴ expresses the threshold pressure P_A as

$$P_A \geq P_H - \gamma P_G - P_V + (P_H - P_G - P_V) \left| \frac{\cos(\alpha_R - \beta)}{\cos(\alpha_A - \beta)} \right| \quad (1)$$

for conditions such that $\alpha_R > \beta$. In equation (1), P_H is the hydrostatic pressure, P_G the equilibrium pressure of the gas dissolved in the liquid, P_V the vapour pressure, γ a constant with value between 0 and 1 which measures the ability of the nucleating gas pocket to maintain the equilibrium gas pressure, β the half-angle of the conical crevice, and α_A and α_R are the advancing and receding contact angles of the liquid–gas interface in the crevice. This equation has been modified as follows to apply it to the experimental situation. It is assumed that during the stabilisation process the interface advances to a specified position and stops. This position determines the diameter of the crevice at the position where the interface meets the crevice wall. It is further assumed that the crevices stabilise in water at normal surface tension and later reduction of surface tension by addition of surfactant does not affect the position of the stabilised interface. The shape of the interface may change but its position in the crevice will not. This assumption allows us to express the quantity $|\cos(\alpha_A - \beta)|$ as a constant, dependent only on the initial value of the surface tension. A second modification of the equation involves the nucleation process. The receding contact angle is affected by addition of a surfactant and its dependence

Fig. 1 a, Scanning electron photomicrograph of a solid impurity. The particle was removed by filtration of distilled water with a 0.45- μm pore size filter, shown as the mottled area in the background. Note the ragged appearance of the surface showing the numerous possible nucleation sites. Scale bar, 5 μm . b, Photograph showing creation and resultant motion of a transient cavity. The cavity was initiated at the centre of a resonating piezoelectric cylinder and was propelled outwards by radiation-pressure forces. Here the flash interval was 2.4 ms, the acoustic pressure amplitude at the antinode was 4.7 bar, and the maximum velocity achieved was about 100 cm s^{-1} . Scale bar, 1 mm.

on surface tension must be specified. This is done by writing $\cos(\alpha_R - \beta) = \cos[\alpha_E - (\alpha_H + \beta)]$ where α_E is the equilibrium contact angle and α_H is the hysteresis between the equilibrium and the receding contact angle. Such a modification allows us to express the receding contact angle in terms of the surface tension. Bargeman and Van Voorst Vader⁷ have found that α_E can be expressed as

$$\cos \alpha_E = -1 + C/\sigma \quad (2)$$

where σ is the surface tension and C is a constant that depends on the surface properties of the solid. For nonpolar solids such as paraffin, and beeswax, $C \approx 50$.

The acoustic cavitation threshold can thus be expressed in terms of measurable parameters as

$$P_A = (P_H - P_V - \gamma P_G) + \frac{(P_H - P_V - P_G)}{\delta} \times \{\cos \phi (C/\sigma - 1) + \sin \phi [1 - (C/\sigma - 1)^2]^{1/2}\} \quad (3)$$

To apply this theory to ordinary water, the unknown parameters, γ , δ and ϕ must be specified. γ is 1.0 for situations in which the gas pressure in the nucleating cavity is maintained at

equilibrium with that in the fluid. As a precise measurement of this constant is impossible, it is assumed that equilibrium will be maintained and thus $\gamma = 1.0$. δ is a parameter which measures the initial value of the advancing contact angle, and is given by $\delta = |\cos(\alpha_A - \beta)|$. Values for the advancing contact angle of

Fig. 2 Variation of the acoustic cavitation threshold of water with (a) dissolved gas content for two values of the liquid surface tension; (b) with surface tension for two values of the equilibrium gas pressure; and (c) with temperature for two values of the equilibrium gas pressure. The curves are for equation (3) with $\gamma = 1.0$, $\delta = 0.035$ and $\phi = 32^\circ$. In (a) Δ and + are experimental measurements from this study and $\circ$ points are values obtained by Strasberg⁶; the frequency in (a) and (b) was 36 kHz and the temperature 25 °C. In (c) the frequency was 22 kHz and the surface tension was 70 dyn cm⁻¹; + points are the normalised values of Galloway¹¹; $\circ$ are measurements from this study. The temperature dependence of the vapour pressure P_v and the equilibrium gas pressure P_g have been inserted into equation (3).

water on nonpolar solids are of the order of 106° . Bargeman⁹ lists values of α_A for four nonpolar solids with an average of 106° , standard deviation 6° ; water on paraffin wax is known to be approximately 106° (ref. 9). α_A was thus selected to be 106° . The crevice angle β is assumed to be small; crevices need small angles for stabilisation; a value of $\beta = 14^\circ$ was selected to give $\delta = 0.035$. Values of the hysteresis angle of water plus surfactant on nonpolar solids were measured by Furmidge¹⁰. He obtained values ranging from 14° to 44° for water plus surfactants on white beeswax. To obtain a good fit to the data, α_H was chosen to be 18° ; hence $\phi = \alpha_H + \beta = 32^\circ$.

The incipient cavitation threshold was measured for acoustic cavitation in distilled water. A hollow piezoelectric cylindrical transducer was used that was open at one end and closed at the other with a thin glass window (thickness 0.01 cm). The thin glass window approximated a pressure-release boundary and the cylinder was driven in a $(r, \theta, z) = (3, 0, 3)$ resonant mode that generated cavitation only along the axis of the cylinder and only at the middle antinode. The height of the cylinder was ~ 7.5 cm, the inside diameter was 7.0 cm, the thickness was 0.5 cm. Figure 1b shows a photograph of a cavitation event that was obtained under stroboscopic illumination. The cavity was created along the axis of the cylinder, approximate centre of photograph, and was propelled outwards by radiation pressure forces¹².

The variation of the cavitation thresholds is shown in Fig. 2a-c respectively: note the excellent agreement with theory. The selection of the parameters γ , δ and ϕ was varied slightly to obtain a best fit but was restricted to lie within the range of measured values. The theory shows no variation with frequency; measurements were made in the low kilohertz region where the measured threshold does not depend upon frequency¹³. For higher frequencies, cavity dynamics are important in determining the threshold^{4,14}.

It is seen that the dynamic tensile strength of distilled water can be accurately predicted if proper account is made of the solid impurity content of the liquid.

Simulated lidar return from a one-dimensional stratospheric aerosol model

RESULTS of theoretical calculations on lidar backscatter from the stratospheric aerosol are presented here. The calculations use the size distribution, particle number density and particle composition predicted by a one-dimensional model of the stratospheric aerosol layer. The theoretically calculated backscatter profile is compared with experimental results obtained from actual lidar observations of the layer.

Fig. 1 a, Scattering ratio (R) as a function of altitude calculated from aerosol model. Dotted lines represent the range of experimental uncertainty (from ref. 11). b, Lidar backscattering ratio obtained 20 September, 1978 with Langley Research Center 48° lidar system.

The one-dimensional stratospheric aerosol model used here is described fully elsewhere¹; therefore we shall give only a few pertinent details. The model assumes that the primary source of sulphur to the stratosphere is biogenic OCS released at ground level². This OCS diffuses into the stratosphere where it is photodissociated, leading to the production of gas phase sulphuric acid. Aerosol droplets are formed by heteromolecular-heterogeneous nucleation of gaseous sulphuric acid and water onto pre-existing solid particles of tropospheric origin. The aerosol particles are spherical, liquid $\text{H}_2\text{SO}_4\text{-H}_2\text{O}$ solution droplets with solid cores. The particles undergo the physical processes of condensation, evaporation, coagulation, sedimentation and vertical eddy mixing³. The model uses these chemical and physical mechanisms to predict altitude profiles for all important aerosol parameters, including the size distribution, number concentration and amount of sulphuric acid in the drops.

Model predictions have been compared with *in situ* measurements of the stratospheric aerosol¹, and agreement is good. Consequently, the model should predict aerosol backscatter ratios reasonably well. However, *in situ* measurements are quite rare above 25 km so they cannot be used to check model results at high altitudes. Therefore, we wish to show that reasonable lidar backscatter profiles can be predicted theoretically using the aerosol model. We also use model results to perform a few simple theoretical 'experiments' to determine how lidar observations will be affected by changes in certain properties of the aerosol layer.

The model simulates a 'background' aerosol; that is, sudden injections of sulphuric gases and particles were not incorporated in the model. Thus, the model results represent the stratospheric aerosol during volcanically quiescent periods. Fortunately, there is a fairly comprehensive lidar record of the aerosol layer over the past decade^{4,5} and much of the data have been obtained during periods of little or no volcanic activity. The last volcano which injected a significant amount of material into the stratosphere was Volcán de Fuego which erupted in October 1974. As

shown by McCormick *et al.*⁶ the volcanic debris in the stratosphere which could be attributed to Fuego decayed away with a $1/e$ time constant of about one year. Before Fuego, a large amount of volcanic matter was injected into the stratosphere by Agung (March 1963). However, just before Fuego, and at present (November 1978), lidar backscatter studies show an aerosol layer close to 'background' levels. Therefore, our theoretical results are compared with data taken either shortly before Fuego or near the present date.

The aerosol parameters used in our calculations are the following: the lidar backscatter intensity was calculated using a Mie model to evaluate the aerosol backscatter coefficient (f_a) for wavelengths $\lambda = 0.6943 \mu\text{m}$ (lidar wavelength) and $\lambda = 1.06 \mu\text{m}$. Both the Mie model and the aerosol model use standard atmosphere⁷ mid-latitude profiles for temperature, density and water vapour. Using the index of refraction data given by Palmer and Williamson⁸ and model results, we determined the altitude dependent index of refraction of the sulphuric acid aerosols. The values varied from 1.41 at 10 km to 1.44 at 38 km. We assumed that the index of refraction of the particles was that of the sulphuric acid-water shell, an assumption which is valid for particles with small cores⁹. The model distinguishes between sulphuric acid aerosol droplets and solid 'condensation nuclei' of tropospheric origin. For the condensation nuclei the real part of the index of refraction was taken to be 1.50, independent of altitude¹⁰.

The results of our calculations are shown in Figs 1-4. These are profiles of the lidar scattering ratio, R , defined by

$$R = \frac{f_a + f_m}{f_m}$$

where f_m is the molecular (Rayleigh) backscattering coefficient.

Figure 1 shows the calculated lidar backscatter ratio at $\lambda = 0.6943 \mu\text{m}$ from aerosol droplets and condensation nuclei between 10 and 40 km altitude. On the same plot we give the range of $\pm$ one standard deviation about the mean measured in 16 lidar observations taken in the period June 1973 to March 1974 by Russell *et al.*¹¹. This was shortly before Fuego so presumably the stratospheric aerosol was primarily non-volcanic in origin. As Fig. 1 shows, the model prediction is in good agreement with experimental results. It should be noted, however, that individual lidar returns show a great deal of structure which is not present in the model. To illustrate this, a typical lidar backscatter ratio profile is shown in Fig. 1b. The structure is probably a result of small scale temperature and

Fig. 2 a, Calculated scattering ratio profiles for different values of real part of index of refraction (η) for wavelength $\lambda = 0.6943 \mu\text{m}$. Curve A1, B1, C1 are for $\eta = 1.3, 1.4, 1.5$, respectively. b, Scattering ratio profiles for wavelength $\lambda = 1.06 \mu\text{m}$. Curves A2, B2, C2 are for $\eta = 1.3, 1.4, 1.5$, respectively.

Fig. 3 a, Calculated scattering ratio profiles for different values of imaginary index of refraction (k) for $\lambda = 0.6943 \mu\text{m}$. Curves A1 and B1 are for $k = 0.00$ and 0.1 , respectively. b, Scattering ratio profiles for $\lambda = 1.06 \mu\text{m}$. A2 and B2 are for $k = 0.00$ and 0.1 , respectively.

water vapour fluctuation and the advection of particles due to stratospheric dynamics. These phenomena are not included in the model. Consequently we can expect agreement between the model and the average of a number of observations, but not for a particular lidar return.

The agreement between model and observation shown in Fig. 1 is particularly striking when one considers the effect of volcanic activity on the lidar returns. For example, post Fuego observations^{3,6} gave scattering ratio (R) profiles that were very sharply peaked and reached maximum values >4 . The pre-Fuego data shown in Fig. 1 (and present day observations of the layer) give maximum values of R of about 1.08.

The calculated lidar signal in Fig. 1 indicates the top of the layer around 35 km. The microphysical processes incorporated in the model result in the evaporation of the sulphuric acid droplets at about 34 km. However, there are some droplets above that altitude due to mixing. Also, the evaporation of the droplets is a source of condensation nuclei (cores). Therefore, the predicted lidar return does not drop off until somewhat above the evaporation level. Lazrus and Gandrud¹² have reported the existence of sulphates up to 36 km, which is slightly higher than indicated by model results or by measurements made with lidar and other methods.

To determine the sensitivity of lidar observations to the index of refraction (η) we carried out calculations varying η for both the aerosol particles and the condensation nuclei. Changes in η for the condensation nuclei did not affect the results because they are so small that they do not contribute significantly to the backscatter. Even the presence of highly absorbing condensation nuclei will hardly affect the lidar return. To verify this we varied the imaginary part of the index of refraction (k) of the condensation nuclei from 0.0 to 1.2 and obtained backscatter profiles which were nearly identical.

However, changes in η for the aerosol particles do affect the backscatter ratio profile. Figure 2a shows calculated profiles assuming η to be 1.3, 1.4 and 1.5. The curves obtained for $\eta = 1.3$ and 1.5 fall outside the range of values given in Fig. 1. This result is significant as it indicates that the index of refraction of the stratospheric particles could be evaluated from lidar returns. (Such an analysis should only be undertaken if the results of many lidar returns are averaged and the atmospheric conditions are comparable to those used in the model. Also one

should have independent information on the size distribution and number density of the particles as these also affect the return). Note that η for ammonium sulphate is slightly greater than 1.5 at $0.6943 \mu\text{m}$. Thus, the results given in Fig. 2a suggest that the aerosol particles are unlikely to be composed of ammonium sulphate, as was believed by earlier investigators of the stratospheric layer.

The value of k for sulphuric acid-water solutions at $0.6943 \mu\text{m}$ is of the order of 10^{-8} and in most of our calculations we used a zero imaginary index. However, to investigate the effect of a large k on lidar backscatter we performed some calculations with $k = 0.1$. It must be emphasised that such a value is many orders of magnitude larger than expected. Nevertheless, as shown in Fig. 3a, the effect on the backscatter ratio profile is not large.

It has been suggested that multi-wavelength lidar studies of the aerosol layer should be carried out. Figures 2b and 3b show the effect of observing the stratospheric aerosol with a $1.06 \mu\text{m}$ wavelength lidar. The most salient characteristic of these figures is the fact that the scattering ratio at $1.06 \mu\text{m}$ is much larger than at $0.6943 \mu\text{m}$. But a comparison of Fig. 2a and b shows that the relative change in scattering ratio with changes in η is nearly the same for both wavelengths. Thus lidar observations at these two wavelengths would apparently give little additional information on the index of refraction. Similarly, comparing Fig. 3a and b we note that a change in λ gives a larger absolute difference between the absorbing and non-absorbing cases, but the relative difference between the two cases is only slightly greater for the larger wavelength.

Meteoritic ablation in the mesosphere might be a significant source of small particles in the stratosphere. To determine the effect of increasing the number of small particles on the lidar return, we incremented the number of condensation nuclei of size $0.01 \mu\text{m}$ radius to a mixing ratio of 800 particles mg^{-1} air above 30 km, and to follow the profile given by Kaselau *et al.*¹³ below 30 km. This enormous increase in small particles had no discernible effect on plotted backscatter ratio profiles. The reason is, of course, that the $0.6943 \mu\text{m}$ backscatter is quite insensitive to small particles. Consequently, one cannot expect lidar studies to determine whether meteoritic ablation contributes significantly to the particulate loading in the stratosphere.

Finally, to evaluate changes in temperature on the lidar return, we calculated the backscatter profile using aerosol model results

Fig. 4 Calculated scattering ratio for different stratospheric temperature profiles. Curve A is for spring/autumn 45° latitude standard atmosphere. Curve B is for July 75° north latitude standard atmosphere.

obtained with a 'warm stratosphere' temperature profile (USA Standard Atmosphere, July, 75° N latitude). The results, presented in Fig. 4, indicate that the lidar returns drop off at lower altitudes, and there is a small decrease in maximum values of the scattering ratio. Calculations using a 'cold stratosphere' (high latitude winter) show a profile extending to higher altitudes, as expected. The model assumes a smoothly varying temperature profile and does not include advection so the sharp peaks in scattering ratio at low temperatures which were noted by McCormick, *et al.*⁶ do not show up in our calculations.

On the detection of lunar volatile emissions

ONE of the most interesting scientific results of the Apollo programme was the discovery that the Moon sporadically releases radiogenic gases¹⁻⁴. It is likely (although not yet proved) that these emissions are correlated with other detectable lunar activity such as shallow moonquakes^{5,8} and the elusive visible events known as 'lunar transient phenomena' or LTPs^{6,7}. Runcorn has argued⁸ that these three types of lunar activity are linked through tidal triggering of cylindrical fault systems around the circular mare, which results in gradual settling of the mascons and venting from the cracks. Considerable evidence exists which favours such a model, including seismic⁹, photogeologic¹⁰ and electromagnetic induction¹¹ data. However, a search for sporadic venting using the Apollo lunar surface Suprathermal Ion Detector Experiments (SIDEs) was unsuccessful¹². This note points out that the SIDE instruments lack the sensitivity to detect even large gas emissions if the venting occurs primarily at a few well-defined LTP sites, and suggests specific flight instruments for the proposed ESA Polar Orbiting Lunar Observatory (POLO) mission^{13,14} which could detect active venting, would help to determine the energy source for LTPs, and would increase our knowledge of lunar geophysics.

It is known that ⁴⁰Ar, ⁴He, and ²²²Rn are outgassed from the lunar interior^{2,4}, where they are formed from the decay of ²³⁸U, ⁴⁰K and ²³²Th. Based on the Rn data, Hodges argues² that the characteristic time for the radiogenic gas release process is ~70 d, with the Rn carried to the lunar surface by the more plentiful Ar and He in an abundance ratio of approximately 137,500:37,500:1 (He:Ar:Rn). The total loss rate for these species from the Moon is about 1.6 × 10³⁰ atoms yr⁻¹ or 1.4 × 10⁴ kg yr⁻¹ with a mean atomic weight of 11.6 AMU. Vondrak³⁰ has calculated the maximum column density ρ of vented gas at an arbitrary distance, R , from a source on the lunar surface. For both direct flux and diffusive transport models, he finds $\rho = S/\epsilon\pi R^2$ provided the gases are not strongly absorbed by the surface, where S is the number of particles released from the (assumed) impulsive point source. Vondrak argues that a gas release would be readily detectable if it increased the column density at one of the three SIDE sites by about a factor of five above the normal lunar dayside density of 10¹² atoms cm⁻². If it is assumed that the vented gases are primarily the He and Ar which are known to be released, rather than CO, CO₂, H₂O and so on as in Vondrak's study (mean atomic weight 32 AMU), his results are modified slightly. Table 1 shows the minimum venting required from one of the six most prominent LTP sites^{6,7} to be detected at a SIDE location. These results indicate that if the lunar He, Ar and Rn vented from the interior are released sporadically at one or more of these LTP sites, it is unlikely that the gas release would have been detected by a SIDE instrument. For example, if half of the released lunar radiogenic He and Ar were to be vented sporadically from the crater Aristarchus and its neighbourhood (where more than one-third of all reported LTPs have been detected)⁷, these events would go unnoticed by the SIDEs. Of course, it is expected that the gases produced in the interior are vented from the Moon at several locations, so that a very large fractional release of the yearly He-Ar-Rn loss is required at one site close to a SIDE to be detectable (for example, one-sixth of the yearly loss vented at the crater Alphonsus in one brief event would be observable at the Apollo 14 site). Therefore the SIDE data are compatible with the other Apollo measurements which indicate sporadic He, Ar and Rn releases.

If the LTP are related to sporadic venting of these radiogenic gases, the detection of such events should be one of the mission objectives of the proposed POLO spacecraft. Previous studies have demonstrated that great difficulties arise in attempts to find energy sources at the lunar surface which could adequately explain the LTP^{7,15}, which in some cases must exhibit a specific lunar surface brightness of at least 1-10 W m⁻² (optical) to be observable from the Earth¹⁶. One process¹⁶ which may be capable of exciting local clouds of He and Ar to the required brightness levels is the Alfvén critical velocity effect^{17,18}. This effect is a nonthermal ionisation process which occurs when a plasma moves through a neutral gas in the presence of a magnetic field at a velocity greater than $\sim(2e\psi/m)^{1/2}$ where ψ and m are the ionisation potential and mass of the neutral atom respectively. The exact mechanisms which transform the relative ion-neutral kinetic energy into heating of the free electrons which must do the ionisation are not fully understood^{19,21}, but the existence of critical velocity phenomena has been

Table 1 Minimum He-Ar release from LTP sites which would be detectable at SIDE locations, after Vondrak³⁰

Vent location	Gas release (kg)		
	Apollo 12	Apollo 14	Apollo 15
Aristarchus	1 × 10 ⁴	1.3 × 10 ⁴	1.8 × 10 ⁴
Alphonsus	4 × 10 ³	2.4 × 10 ³	1.4 × 10 ⁴
Plato	2.6 × 10 ⁴	2.5 × 10 ⁴	5.8 × 10 ³
Gasendi	3.6 × 10 ³	5.4 × 10 ³	3.0 × 10 ⁴
Agrippa	1 × 10 ⁴	7.3 × 10 ³	4.0 × 10 ³
Proclus	4.4 × 10 ⁴	3.6 × 10 ⁴	1.4 × 10 ⁴

established in laboratory experiments²⁰ and possibly on the lunar surface²². The interaction between the solar wind and an emitted He-Ar cloud should exhibit this effect, although there are uncertainties due to scaling from the laboratory experiments to the lunar situation¹⁶. The supermagnetosonic plasma-neutral interaction should be characterised by the emission of radiation, primarily at infrared and longer wavelengths, which is partially plane polarised relative to the ambient magnetic field²³. This polarisation is a result of the nonlinear plasma processes in the interaction which create a population of nonthermal electrons in the interaction region with velocities primarily along the magnetic field direction. Unlike other proposed energy sources for LTP, this critical velocity model relies on internal lunar energy for the phenomena. The thermal energy of the escaping neutral gas is converted into free electron energy by the plasma interaction, and then into radiation by coulomb excitation of neutrals. That is, the magnetised solar wind acts like an electromagnetic catalyst which converts the expansion energy of the gas cloud into visible photons.

In addition to the other experiments¹³ which should be included on a lunar survey mission, a POLO spacecraft should carry instruments to detect and analyse the sporadic venting of lunar radiogenic gases. These should include: an α -particle spectrometer² to measure the ²²²Rn and ²¹⁰Po distributions on the lunar surface²³ and thus indicate regions where recent venting has taken place⁴; a combined infrared spectrometer/polarimeter to determine the surface mineralogy by reflectance spectra^{24,25} and to search for the He and Ar emission lines expected in the plasma-neutral interactions^{16,26,27}; and a low-to-medium energy charged particle detector capable of both high spatial (pitch angle) and energy resolution. The last instrument could map the lunar surface remanent magnetic fields using the electron reflection technique^{28,29}, and could search for bursts of low energy (80–100 eV)^{26,27}, low pitch-angle (relative to the solar wind magnetic field) nonthermal electrons generated in gas clouds vented from the Moon by the proposed critical velocity effect.

Palaeomagnetic field strengths from sediments baked by lava flows of the Chaîne des Puys, France

MEASUREMENTS of ancient geomagnetic strength are of great interest but are much less common than measurements of direction. This is due partly to the scarcity of materials which are both well dated and suitable for study, and partly to the amount of time required to make measurements using presently available techniques. We report here three new results from baked sediments which have been dated by thermoluminescence (TL) or radiocarbon methods. One of them is early Holocene and the others are late Pleistocene (Table 1). The localities have been described by Huxtable *et al.*¹, from whom we obtained samples.

Laboratory measurements were performed on cubic specimens (23 mm edges, cut from the samples), using a 'Digico' magnetometer with an 80-mm diameter balanced fluxgate detector². Directions of natural remanent magnetisation (NRM) from those samples which were orientated have been discussed elsewhere¹.

Ancient field strengths were determined using the modified Thelliers' technique^{3–5}, which involves reheating specimens to progressively higher temperatures and comparing the ancient magnetisation with a new one acquired in a known laboratory magnetic field. Two heatings were performed at each temperature, using a furnace of the type described by Barbetti⁶ inside the Rubens coil system constructed by Weaver¹⁰. The first heating and cooling cycle at each temperature was performed in zero magnetic field, and the second in a magnetic field of 48.5 μ T. Measurements of remanent magnetisation were made at room temperature after every heating; values of the partial NRM (PNRM) remaining were obtained from the first of each pair of measurements, and values for the newly acquired partial thermoremanent magnetisation (PTRM) were obtained by vector subtraction between the pairs of measurements for each heating temperature.

The measurements were analysed in the normal way by constructing an NRM-TRM diagram, in which PNRM values are plotted against PTRM values with heating temperature as a parameter^{7,8}. Lines were fitted to appropriate sets of points using the 'maximum likelihood' method¹¹, assuming that errors in the PNRM and PTRM are normally and identically distributed but uncorrelated. The slopes of the fitted lines are a measure of the ratio of NRM to TRM, and estimates of ancient field strength are derived on the basis that the magnetisations are proportional to the magnetic fields in which they were acquired.

The results are summarised in Table 1, and representative NRM-TRM diagrams are shown in Fig. 1. Decisions about which points to include in the line-fitting analyses were made in an empirical fashion. Trial analyses were performed for each specimen and the high-temperature points progressively excluded until the width of the calculated confidence limits approached a minimum; final choices were made for each site after inspection of the results from the appropriate group of specimens.

Five of the St Saturnin specimens (from three black-coloured samples) gave consistent (though somewhat variable) results with a mean of $79 \pm 14 \mu$ T. Two specimens from sample i15 gave much lower values (Table 1 and Fig. 1), and have therefore been excluded from the mean. The low values might be explained by deformation or the introduction of small quantities of fine-grained material after the ancient baking, or they may be related to some peculiarity in the magnetic mineralogy.

Five red-coloured specimens from Royat gave highly consistent results (Table 1). The NRM-TRM diagrams (see Fig. 1) exhibited linearity over wide temperature ranges, with small departures (decreases in PTRM-carrying capacity) above 600 °C; they rank among the best we have ever obtained from

Fig. 1 Representative NRM-TRM diagrams. The units are $\text{mA m}^2 \text{kg}^{-1}$, the horizontal scales are twice the vertical ones, and numbers near the points give the laboratory heating temperatures in $^{\circ}\text{C}$. Lines have been fitted to the sets of points represented by solid symbols. The dashed line for Royat specimen j4/4 has been fitted to the points from 388°C to 555°C ; it has a slope $\sim 25\%$ lower than the solid line and is thought to result from the introduction of new sediment after the ancient baking.

ancient materials. We also analysed specimen j4/4, from a separate sample which contained a small ($\sim 1\%$) but clearly visible proportion of grey-green clay distributed along internal fracture surfaces. Four points on the NRM-TRM diagram (Fig. 1) between 147°C and 315°C gave a result (Table 1) identical to the mean value of the other specimens, whereas the points from 388 to 555°C lie on a well defined line with significantly lower

slope. These observations agree with what one might reasonably expect; that the introduction of sediment after the ancient baking should make little difference to the PNRM but a great deal of difference to the PTRM, particularly at temperatures above $\sim 300^{\circ}\text{C}$ when minerals such as goethite may be transformed to haematite¹².

The four red-coloured specimens from Boissejour gave very

Table 1 Summary of ages and palaeomagnetic field strength measurements

			Mean	20 ± 1	

Provenance of the samples is given in ref. 1, specimens are identified by sample code and individual numerals after the slash. Column 4 gives the temperature range and number of points used in the final line-fitting analyses on the NRM-TRM diagrams. Estimates of ancient field strength are given with 95% confidence limits for each specimen, and site mean estimates are listed. Dipole moments have been calculated using the palaeomagnetic direction for Royat³ (to give a virtual dipole moment; ref. 4) and the axial dipole inclination for the other two sites (to give virtual axial dipole moments); the 95% confidence limits include contributions from the uncertainties in both strength and direction (α_{95} taken as 20° for St Saturnin and Boissejour).

similar results. An unusually large proportion of the total magnetisation (both NRM and TRM) was associated with temperatures below ~250 °C, suggesting the presence of a mineral (such as titanomagnetite) with a low Curie temperature in addition to the usual magnetic minerals with Curie temperatures above 550 °C. The specimens exhibited a noticeable decrease in PTRM-carrying capacity at temperatures above 460 °C (see Fig. 1), and the higher-temperature points have been excluded from the final line-fitting analysis.

Mean values of ancient field strength, and corresponding values for the geomagnetic dipole moment, are given in Table 1. These results have several implications. First, the value for St Saturnin is higher than the present-day dipole moment (8.0×10^{22} A m²). That confirms previous results obtained by Bucha^{13–15} from Çatal Hüyük in Turkey (mean 10.0×10^{22} A m²), but is somewhat higher than results from Japan¹⁶ (mean 6.1×10^{22} A m²). An average of those and the St Saturnin result yields a dipole moment of 9.6×10^{22} A m² for the period 8,200–7,000 conventional radiocarbon yr ago.

The virtual dipole moment for Royat (Table 1) is low and the palaeomagnetic direction (295.5°, +66.5° which is 26° from the axial dipole direction for the site) is also unusual³. The TL ages for Royat¹ and the Laschamp event (33,000 ± 4,000 yr; refs 17, 18) are not significantly different, and they may be linked as previously suggested³. Also the Laschamp event may have occurred at the same time as the Lake Mungo geomagnetic excursion in Australia¹⁹ (which has a very similar TL age of 33,500 ± 4,300 yrs; ref. 20), and that the Royat flow may have occurred up to a few thousand years later (perhaps at the same time as the younger excursion at Lake Mungo when low values were recorded for dipole moment¹⁹). It is also interesting that a double-excursion occurred at around the same time at Mono Lake in California²¹.

The result for Boissejour (Table 1) indicates a low geomagnetic dipole moment at an earlier date. The possible effects of

geomagnetic strength variation on the radiocarbon time-scale for the late Pleistocene will be discussed in a forthcoming paper.

We thank J. Huxtable, M. J. Aitken and N. Bonhommet for the samples and encouragement. The measurements were made in the archaeomagnetic laboratory at the Research Laboratory for Archaeology and the History of Art, Oxford University. The laboratory and K.F. were supported by grants to Dr M. J. Aitken from the NERC and the Pilgrim Foundation, and M.B. was supported from funds provided by Professor E. T. Hall and the late Major Hall.

Preferential formation of the atmosphere-sialic crust system from the upper mantle

IN the past decade, extensive studies of the rare gas content of mantle derived rocks have led to several models of Earth degassing, all of which assume that the argon of the atmosphere degassed from the entire mantle. We give evidence here to support the concept of concurrent transfer of elements to the atmosphere and sialic crust preferentially from the upper mantle. This concept accounts for the following observations: (1) the ^{40}Ar concentrations in the rapidly quenched glassy margins of deep sea pillow basalts are too low for many estimates of the K concentration of the mantle^{1,2}; (2) the $^{40}\text{Ar}/^{36}\text{Ar}$ ratio of rocks derived from the deep mantle is similar to the atmospheric $^{40}\text{Ar}/^{36}\text{Ar}$ ratio³⁻⁷; (3) the upper mantle under oceanic ridges is depleted in K and other large-ion-lithophile elements. A schematic representation of the upper mantle depletion process is given in Fig. 1 which shows that partial melting associated with spreading ridges and Benioff zones exclusively in the upper mantle is responsible for the accretion of continents and associated degassing to the atmosphere.

The concentration of argon in glassy margins of submarine basalts provides evidence for depletion of argon in the upper mantle. Several factors can affect the composition and concentration of argon isotopes in submarine basalts, but degassing and contamination by atmospheric argon probably dominate⁸. The effect of atmospheric mixing is demonstrated in Fig. 2. In this type of plot, mixtures of atmospheric argon with a uniform source of mantle argon will form a line with a slope equal to ^{40}Ar content of the mantle and which connects the atmospheric and mantle $^{40}\text{Ar}/^{36}\text{Ar}$ values. Figure 2 shows basalt samples forming a broad mixing band between $^{40}\text{Ar}/^{36}\text{Ar}$ ratios above 10,000 and the atmospheric value of 295.5. The scatter in the data may be attributed to degassing which affects the $1/^{36}\text{Ar}$ values but

not the $^{40}\text{Ar}/^{36}\text{Ar}$ value. Concentration of argon into the melt during partial melting may contribute to the scatter, but probably to a lesser extent⁸. A maximum of $3.22 \times 10^{-6} \text{ ml g}^{-1}$ is derived for the ^{40}Ar concentration of the mantle source from the slope of the steepest mixing line in Fig. 2. We consider this value to be a maximum, not only because of the rather striking upper limit exhibited by the mixing line, but also because the ^{40}Ar concentration measured on what may be the least degassed oceanic ridge sample available, a 'popping rock' recovered from 5,750 m in the Cayman Trough, is $2.0 \times 10^{-6} \text{ ml g}^{-1}$, well below this value. Furthermore, 65% of all the ^{40}Ar concentrations measured form a distinctive peak between 0.9×10^{-6} and $3.0 \times 10^{-6} \text{ ml g}^{-1}$ with the other 35% of the data scattered between 0.9×10^{-7} and $0.9 \times 10^{-6} \text{ ml g}^{-1}$ (ref. 2).

The concentration of ^{40}Ar in the oceanic crust can be used to compute the original K content of the mantle by calculating the 'reconstituted' concentration of ^{40}Ar , that concentration of ^{40}Ar that would now exist in the mantle if it had never degassed ^{40}Ar to the atmosphere. Previously published estimates of reconstituted ^{40}Ar have assumed the atmospheric ^{40}Ar degassed from the entire mantle. In the preferential degassing model presented here, the mass of the mantle from which the atmosphere-sialic crust ^{40}Ar was derived, is allowed to vary from 0 to 100% of the total mantle and the reconstituted ^{40}Ar is calculated according to the formula

$$\Sigma^{40}\text{Ar} = [^{40}\text{Ar}_m] + \frac{^{40}\text{Ar}_{at} + ^{40}\text{Ar}_s}{xM} \quad (1)$$

where; $\Sigma^{40}\text{Ar}$ = the reconstituted ^{40}Ar , the concentration of ^{40}Ar that would exist in the mantle today after returning the ^{40}Ar from the atmosphere and sialic crust to the portion of the mantle from which it degassed; $[^{40}\text{Ar}_m]$ = the concentration of ^{40}Ar now in the depleted mantle, here represented by the ^{40}Ar in glassy submarine basalts; $^{40}\text{Ar}_{at}$ = the mass of ^{40}Ar in the atmosphere; $^{40}\text{Ar}_s$ = the mass of ^{40}Ar in the sialic crust, estimated by assuming that the K content of the sialic crust is 2.5% and the average argon retention age 2,000 Myr; x = the fraction of the mantle from which the atmosphere and sialic crust formed; M = the mass of the mantle ($42.56 \times 10^{26} \text{ g}$).

The original K content of the mantle can be calculated from ^{40}Ar assuming an age 4,500 Myr for the Earth. The results are depicted in Fig. 3, which plots $[^{40}\text{Ar}_m]$ versus the per cent of the mantle degassed. As shown in Fig. 3, if the ^{40}Ar content of glassy submarine basalts represents the maximum ^{40}Ar of the depleted mantle today, and the atmosphere degassed from the entire mantle, then the original K content of the mantle was <200 p.p.m. An original K content of the Earth this low is

Fig. 1 Diagrammatic representation of preferential formation of the atmosphere and sialic crust from the upper mantle.

incompatible with many whole-Earth heat flow models. Higher values for the original K content are allowed if the atmosphere and sialic crust degassed preferentially from the upper mantle.

Further implications of the concept of preferential degassing of the atmosphere can be demonstrated by constructing a model of Ar and K distribution in the Earth based on the following constraints: (1) the atmosphere-sialic crust system formed from the upper 415 km of the mantle. (2) Degassing of ^{40}Ar took place, with simultaneous transfer of K to the sialic crust⁹. (3) The maximum ^{40}Ar of the depleted upper mantle is equivalent to the maximum ^{40}Ar in glassy submarine basalts (see Fig. 2).

The first constraint limits the zone of preferential depletion to the upper 415 km, or about 25% of the total mantle. The 415-km seismic step depth was chosen because of a seismic velocity increase which corresponds to a transition from a zone of low density to a zone of high density and may represent a transition from depleted to non-depleted mantle. If it is assumed that all the atmospheric ^{36}Ar degassed from the depleted zone, it is possible to calculate that the ^{36}Ar of the non-depleted mantle is $\sim 10^{-7} \text{ ml g}^{-1}$. The second constraint specifying coherency between argon degassing and K transfer is justified because all of the ^{40}Ar of the atmosphere can be produced from a sialic crust containing a 2.5% K (ref. 9). The actual value of K may be as low as 1.25%, therefore the amount of K which must be depleted from the upper 415 km of the mantle to produce the sialic crust ranges from 240 to 475 p.p.m. Constraint (3) permits calculation of ^{40}Ar of the non-depleted lower mantle (see equation (1)), which for preferential degassing to 415 km is calculated to be $4.5 \times 10^{-5} \text{ ml g}^{-1}$. The $^{40}\text{Ar}/^{36}\text{Ar}$ of the non-depleted mantle ($4.5 \times 10^{-5}/1.0 \times 10^{-7}$) is 450. The original K content of the non-depleted mantle is calculated from $\Sigma^{40}\text{Ar}$ and the stipulation of degassing to 415 km and is found to be 660 p.p.m. (Fig. 3). By subtracting the K removed to the sialic crust, the K content of the depleted mantle is calculated to be 125–422 p.p.m.

All the results of the model calculations are summarised in Table 1. This model is not presented as a unique solution for the preferentially degassed mantle, but rather as a starting matrix

Fig. 2 The $^{40}\text{Ar}/^{36}\text{Ar}$ ratio compared with the $1/^{36}\text{Ar}$ ratio in glassy submarine basalts. This plot is used to demonstrate the effects of mixing atmospheric argon ($^{40}\text{Ar}/^{36}\text{Ar} = 295$) with mantle argon of high $^{40}\text{Ar}/^{36}\text{Ar}$. The dashed line probably represents the mixing line of steepest slope and may correspond to the maximum ^{40}Ar of the oceanic crust. The data are from refs 8, 15–17 and unpublished.

from which more sophisticated solutions can evolve. Several possible perturbations on the model are envisaged.

First, loss of ^{40}Ar to the atmosphere from upper mantle without simultaneous transfer of K to the sialic crust would increase the K content of the depleted upper mantle while decreasing the K content of the sialic crust, but would not change the K content of the non-depleted mantle.

Second, modification of the thickness of the zone of depletion can decrease or increase possible solutions for the K and Ar contents of the mantle, but would not change the solutions for the K content of the sialic crust.

Third, if the K concentration of the sialic crust is less than 2.5%, a higher percentage of ^{40}Ar must have degassed directly from the mantle without coherent formation of the sialic crust. This would result in higher K concentrations for the depleted mantle. Furthermore, the ^{40}Ar of the sialic crust would be lower than the value used in this model to calculate $\Sigma^{40}\text{Ar}$ and would result in lower solutions for the K content of the non-depleted mantle. For example, if the K concentration of the sialic crust is 1% instead of 2.5% as used in the model calculation, $\Sigma^{40}\text{Ar}$ and K concentration of the non-depleted mantle would be 13% lower.

Several implications of the idea of preferential degassing can be tested by comparing data on samples thought to represent the

Fig. 3 The ^{40}Ar content of the present day upper mantle compared with the per cent of the mantle from which the atmosphere-sialic crust formed. The iso-K curves represent solutions of the initial K content of the mantle derived by recombining the atmospheric-sialic component of ^{40}Ar with the ^{40}Ar presently in the depleted portion of the mantle.

depleted and non-depleted mantles. Ocean ridge basalt probably originated in the depleted zone, while basalts associated with 'plumes' and many continental ultramafics may originate in the deep mantle. The most reliable samples of deep mantle may be continental ultramafic rocks containing anomalous ^3He , ^{21}Ne , or ^{129}Xe or exhibiting a 'planetary' type rare gas abundance pattern. The planetary-type rare gas abundance pattern is characterised by a high $^{84}\text{Kr}/^{130}\text{Xe}$ ratio compared with the atmosphere ratio and a low $^{20}\text{Ne}/^{36}\text{Ar}$ ratio compared with the ratio in oceanic ridge basalts¹⁰. Deep mantle-derived samples include: a kaersutite inclusion in nephelinitic basalt from New Zealand containing excess ^3He and ^{21}Ne and exhibiting a planetary rare gas abundance pattern³; josephinite, a rare terrestrial nickel-iron alloy containing elemental silicon and thought by some to have originated from the core-mantle boundary and containing excess ^3He , ^{21}Ne , and ^{129}Xe ^{6,7}; a kearsutite inclusion in alkali basalt from Dish Hill, California, containing excess ^3He and exhibiting a planetary type rare gas abundance pattern⁵; two olivine megacrysts from South African

kimberlite pipes containing excess ^3He and ^{129}Xe and a planetary rare gas abundance pattern and samples of kimberlite, carbonatite and diamond from South Africa^{5,11}.

The model calculations imply that the $^{40}\text{Ar}/^{36}\text{Ar}$ ratio of the deep mantle is similar to that of atmosphere (see Table 1). This stems from the assumptions that the deep mantle has remained a closed system and the atmosphere now contains more than 80% of all the ^{40}Ar and more than 99% of the ^{36}Ar that would have currently been in the upper mantle if it had remained a closed system. It is also important that according to the model calculations the upper mantle has been depleted in ^{36}Ar by a factor of >100 whereas it has been depleted in K by a factor not greater than 6; the net result being, that $^{40}\text{Ar}/^{36}\text{Ar}$ ratios as high as 16,000 can be expected in the depleted upper mantle. A comparison of the available data with the model is summarised in Fig. 4 which is a histogram comparing the $^{40}\text{Ar}/^{36}\text{Ar}$ ratio in basalts dredged from plume areas and continental ultramafics uncontaminated by crustal material, with submarine ridge basalts. The $^{40}\text{Ar}/^{36}\text{Ar}$ of the plume basalts and ultramafics range from 295 to 1,200 with the majority falling below 500, while ridge basalts range up to 16,000 with the majority falling above 1,000. It is interesting that, all continental ultramafics containing ^3He , ^{21}Ne , or ^{129}Xe , have a $^{40}\text{Ar}/^{36}\text{Ar}$ ratio below 850. This observation has led several workers to suggest that the $^{40}\text{Ar}/^{36}\text{Ar}$ ratio of the mantle source is similar to that of atmosphere³⁻⁵. The possibility of a mantle with a low $^{40}\text{Ar}/^{36}\text{Ar}$ ratio was first proposed on the basis of the initial ratio derived from K-Ar isochron plots of basalts and dolerites¹², although these samples may have been contaminated by atmospheric or crustal argon. For deep mantle ultramafics which have excess ^3He and relatively low $^{40}\text{Ar}/^{36}\text{Ar}$ ratios, crustal contamination can be ruled out because of the high concentrations of ^4He in crustal rock. On the other hand, the high concentration of ^{36}Ar in the atmosphere makes it conceivable that atmospheric contamination after extrusion has produced the low $^{40}\text{Ar}/^{36}\text{Ar}$ ratios without completely eradicating the other rare gas isotopic anomalies. However, stepwise heating experiments on low $^{40}\text{Ar}/^{36}\text{Ar}$ ultramafics have demonstrated the low ratio exists even in the high temperature fractions which are least likely to be contaminated by atmospheric argon⁴.

The model presented above also requires that the deep-mantle samples have higher rare gas contents than upper mantle samples. The evaluation of this implication from existing data is difficult because crustal contamination and degassing may have altered the concentrations. The ^{36}Ar concentration in the glassy margins of oceanic basalts is variable, but after accounting for the effects of atmospheric contamination and degassing, the ^{36}Ar concentration of the upper mantle under oceanic ridges has been estimated to be $<2 \times 10^{-10} \text{ ml g}^{-1}$ (ref. 1). With the exception of diamonds, the available ^{36}Ar data on the continental ultramafic samples used in Fig. 4 fall in the range $0.38\text{--}3.6 \times 10^{-8} \text{ ml g}^{-1}$, distinctly higher than estimates of the ^{36}Ar in the upper mantle under the oceanic ridges. The high abundance of ^{36}Ar in these samples may reflect the ability of these minerals to preferentially accommodate rare gases in their structure relative to other phases in the mantle and does not prove that the deep

mantle has a higher concentration of rare gases than the upper mantle. Nonetheless, the data are consistent with and support the model of preferential degassing of the upper mantle. The only ultramafic samples known at present with anomalous ^3He or ^{129}Xe , which have $^{40}\text{Ar}/^{36}\text{Ar}$ ratios $>1,000$, are ultramafic xenoliths from Hawaii^{12,13}. This observation may reflect the possibility that the mantle is more extensively depleted in oceanic regions than under the continents, or that these xenoliths originated in the depleted upper mantle.

The concept of preferential formation of the atmosphere and sialic crust from the upper mantle provides a means of depleting K and other incompatible elements in the mantle beneath oceanic ridges and is consistent with rare gas data on mantle derived rocks. It is especially useful in accounting for possible similarities in the $^{40}\text{Ar}/^{36}\text{Ar}$ ratio of the atmosphere and rocks of deep mantle origin.

This work was supported by NSF grants OCE76-82015 and

Sapphirine-bearing rocks with sedimentary and volcanogenic protoliths from the Arunta Block

At least 15 separate localities for sapphirine-bearing rocks have been found in the Arunta Block, a Precambrian metamorphic complex in central Australia (Fig. 1), although only two have been documented in any detail¹⁻³. Such rocks are the most spectacular examples of a suite of rocks with a distinctive, characteristic chemistry. This suite includes, *inter alia*, the better known cordierite-anthophyllite rocks, and is widely distributed both within the Arunta Block and world-wide. From field observations it is proposed here that two different geological processes, one sedimentary or diagenetic and the other volcanic, generated rocks that are now indistinguishable in their whole-rock chemistry and mineral assemblages. It had formerly been proposed that sapphirine-bearing rocks of volcanogenic and sedimentary origins were mineralogically and chemically distinct⁴.

Rocks in this chemical suite have compositions in which >90% of the oxide total is contributed by SiO₂, Al₂O₃, MgO, and FeO; representatives are either silica-undersaturated or contain only small quantities of modal quartz. Metamorphic grade affects the proportion of modal quartz for a given SiO₂ content, as well as the other minerals which may include talc, chlorite, phlogopite-biotite, anthophyllite, gedrite, cummingtonite, cordierite, sillimanite, kyanite, corundum, staurolite, orthopyroxene, kornerupine (boron-bearing), garnet, sapphirine and spinel. These minerals and whole-rock compositions may be shown diagrammatically on a quaternary SiO₂, Al₂O₃, and MgO+FeO plot (Fig. 2). Such a plot cannot take account of the effect of MgO/FeO on mineral assemblages: staurolite and garnet may occur if MgO/FeO (whole-rock composition) is low, whereas sapphirine requires high MgO/FeO. The effects of metamorphic facies and variations within the chemical constraints are shown in Table 1, using examples from various localities within the Arunta Block.

Whole-rock analyses from the chemical suite define a trend slightly more aluminous than the tie quartz-chlorite in Fig. 2, as do estimates of composition derived from mineral assemblages. This agrees substantially with previously published statements^{5-7,14} that some cordierite-anthophyllite rocks originated as chlorite-rich rocks, but implies an additional aluminosilicate component, such as kaolinite, illite, phengite, muscovite or feldspar. Sapphirine-bearing rocks (and hypersthene-garnet-bearing rocks), being higher metamorphic facies equivalents of cordierite-anthophyllite rocks, may have similar origins. Figure 2 also shows that even apparently 'sedimentary-type' sapphirine-bearing rocks could not have originated as mixtures of clay minerals, although for such rocks magnesite-rich protoliths should be considered.

On the basis of geological setting two major groups of rocks belonging to the chemical suite are recognised in the Arunta Block.

Group 1: sedimentary type. In the Reynolds Range sapphirine-bearing and chemically akin rocks crop out intermittently over a kilometre along the (regional) unconformity between an eroded sequence of pelites and an overlying quartzite⁸. Similar rocks, also sapphirine-bearing, crop out in the same stratigraphic position, some 10 km to the east, and similar, though slightly more siliceous, rocks crop out on the same unconformity several kilometres to the south. A hundred kilometres to the east, near Delmore Downs, specimens of quartz-chlorite-anthophyllite-cordierite granofels have been collected at the same regional unconformity. In the Reynolds Range a pod of sapphirine-anthophyllite-cordierite-enstatite granofels with cordierite-rich granofels also occurs several hundred metres above the unconformity within a pelitic sequence.

The geological processes that generated these magnesian minerals must have been compatible with the deposition and diagenesis of the enclosing non-volcanic sedimentary sequences. A possible protolith would be a mixture of magnesite, a clay (illite or kaolinite), haematite and quartz (see ref. 9) formed by surface waters with high pH and CO₂ content. An alternative origin might have been by way of meerschaum or sepiolite deposits generated from alkaline groundwaters¹⁰. As these rocks are low in CaO, they are not metamorphosed marls, unlike the sapphirine-bearing rocks of southern Madagascar¹¹. These rocks contain appreciable FeO, and include examples lower in SiO₂ when compared to the chemically similar white schists of sedimentary origin in Zambia and Afghanistan¹².

Group 2: volcanic type. Rocks belonging to the chemical suite are also widely distributed in the granulite terrain of the Harts and Strangways Ranges within metamorphosed volcanic and volcanoclastic sequences of acid and basic composition¹³. Occurring as pods and layers associated with distinctive cordierite quartz-rich granofels, they are subdivided on field setting into two subclasses. Those with discordant relationships originated as chlorite-rich pods within zones of extensive chloritic alteration cross-cutting the original volcanic stratigraphy. Others occur as a concordant basal layer in a three-tier

association with impure marbles and/or calc-silicate granofels and banded gneisses consisting of quartz and iron minerals (magnetite, grunerite, and so on). These are interpreted as metamorphosed distal deposits from exhalative activity (Fig. 3). At some localities both subclasses crop out in close proximity; elsewhere only one type is present. This interpretation is similar to that proposed for some cordierite-anthophyllite rocks in the Canadian Shield^{6,14}, an interpretation enhanced by the presence of pyrite, galena, sphalerite, and chalcopyrite in many of the layered outcrops¹⁵. Sapphirine-bearing outcrops in the Yilgarn Shield have been interpreted as altered mafic volcanic rocks¹⁶. Relatively unmetamorphosed per-magnesian chloritic rocks of volcanic origin are rare but are known, for example, from the Woodlawn orebody in southeastern Australia¹⁷. Previously sedimentary origins have been proposed for some sapphirine-bearing (and chemically related) rocks in the Strangways Range^{3,18}.

Only field relationships are presently useful in distinguishing the two groups. Chemical analyses (from the Arunta Block and elsewhere) of the two types show such an overlap (see Fig. 2) that they provide no obvious discriminants.

Several outcrops shown in Fig. 1 were discovered by other members of a project team from the Bureau of Mineral Resources studying the Arunta Block. Constructive criticism and discussion proffered by colleagues at BMR and the Northern Territory Geological Survey, and by B. J. Hensen, N. Herriman, D. F. Sangster, W. Schreyer, and R. H. Vernon is

Sediment loads in the Amazon River

ESTIMATES published in the past 20 years of the sediment load delivered to the sea by the Amazon River range from 4 to 10×10^8 tonnes yr^{-1} . Estimates published around 1960, when few data were available on either the sediment concentration or the river discharge, were in the range $9\text{--}10 \times 10^8$ tonnes yr^{-1} (refs 1, 2). Estimates published in 1967 and 1968, after significant new data had been collected, were in the lower range of $4\text{--}5 \times 10^8$ tonnes yr^{-1} (refs 3, 4). Our more comprehensive data collected mostly since 1970 (and especially in 1977) suggest that the earlier higher estimates may have been more nearly correct. We show here that the mean annual load of suspended sediment at Óbidos, Brazil is between 8 and 9×10^8 tonnes yr^{-1} . Most of this sediment is discharged onto the continental shelf.

During the high-water seasons of 1976 and 1977, we measured sediment loads in the Amazon River basin. Our most

complete set of measurements were made during May and June of 1977, when we followed the annual high-water stage down the Amazon and measured the suspended-sediment loads at six places on the mainstem and in the two largest tributaries (Fig. 1). Because our ship moved downriver at about the same speed as the flood wave (considering the sampling stops we made en route), we came close to following the same relative flood stage for about 3,000 km from Peru to near the mouth of the Amazon. This gave us added insight into how the sediment load changed downriver.

The amounts of sediment being carried in suspension in 1977 were measured in samples of river water collected from RV Alpha Helix with a large-volume, depth-integrating sampler. The depth-integrating sampler is lowered to the river bed and raised back to the surface at a uniform vertical rate; its intake nozzle is designed to admit the sediment-water mixture at stream velocity. The resulting sample is thereby weighted for differences in velocity in different parts of the water column. One only need multiply the concentration of sediment measured in such a sample by the corresponding water discharge to obtain the suspended-sediment load^{5,6}. At each of the locations listed in Table 1, we took depth-integrated samples at three to seven stations spaced more or less evenly across the width of the river. Further information on our sampling and laboratory procedures, as well as a complete tabulation of the suspended-sediment data, are published elsewhere⁷.

Water discharges reported in Table 1 for the five mainstem sections in Brazil were estimated from the stage-discharge relationships (rating curves) that have been developed for these stations by Hidrologia S.A. and Companhia de Pesquisa de Recursos Minerais (CPRM). River stage is measured daily and river discharge is measured monthly or bimonthly at these stations. At Iquitos, where no independent measurements were available, we made a rough calculation of water discharge from our velocity data and the area of the cross-section measured by sonar (depth) and radar (width). The discharge of the Rio Madeira is estimated from measurements that Hidrologia S.A. makes monthly at its furthest downstream gaging station on the Madeira, about 200 km upriver of where we collected samples of suspended sediment. Discharge of Rio Negro, whose flow is not measured, was estimated from the difference between discharge at Óbidos and at other measured and unmeasured tributaries as detailed in the footnote to Table 1.

Suspended-sediment loads remain fairly constant in the mainstem between Iquitos and Manacapuru, indicating that the sediment in this part of the river is derived from the Andes while the jungle-draining tributaries that enter the river in Brazil bring in large amounts of water but little additional sediment. This

Fig. 1 Map of Amazon River, showing locations on mainstem and tributaries where sediment loads were measured in 1977.

feature was noted earlier by Sioli⁸ and was elucidated by Gibbs³, who estimated that 82% of the suspended solids discharged by the river were derived from the 12% of the total area of the Amazon basin that lies in the mountainous terrain of the Andes. The epitome of the jungle tributaries is Rio Negro which contributes ~20% of the water flow of the total Amazon system but only a trivial proportion of the sediment. Rio Madeira, on the other hand, has its headwaters in the Andes of Bolivia, and it carries a significant load of sediment.

The downstream decrease in the discharge-weighted concentrations shown in Table 1 was noted earlier by Gibbs³, but our data disagree with his in several places (Fig. 2). We were unable, in either 1976 or 1977, to detect the concentrations $>400 \text{ mg l}^{-1}$ that Gibbs reported during high-water seasons in the upper river. At Óbidos in the lower river, we measured higher concentrations than he did. After discussions with Gibbs we agree that the differences between our data and his are probably related to differences in sampling procedure. However, this does not rule out the possibility that the differences are real differences between one year and another.

Because the data in Table 1 represent only a single day's sediment load near the annual peak of river flow, we cannot extrapolate the figures by themselves to obtain long-term loads. However, by combining our sediment data with other unpublished data on the annual cycle of river discharge and the concentration of suspended sediment at low discharge, we can make a new estimate of the average annual load of suspended sediment at Óbidos. The section at Óbidos is the furthest downstream point on the mainstem at which river discharge is measured regularly.

The mean monthly discharges at Óbidos for a 4-yr period are shown in Fig. 3a. These averages were computed from the daily measurements of river stage and the less frequent (mostly bimonthly; some monthly) measurements of river discharge that were made in this period by CPRM and Hidrologia S.A. for the Departamento Nacional de Águas e Energia Elétrica (DNAEE).

The concentration of suspended sediment at low water was measured at Óbidos on 21 November 1963, by Ames of the

Fig. 2 Concentrations of suspended sediment in Amazon River mainstem. Solid lines represent concentrations reported by Gibbs³ for wet, intermediate, and dry seasons. Dark circles are the discharge-weighted concentrations listed in Table 1.

USGS during the first concerted efforts to measure the flow of the Amazon⁹. River discharge on that day was measured at $72,500 \text{ m}^3 \text{ s}^{-1}$. Ames collected 13 point samples of suspended sediment from different depths and at different locations across the river, and he calculated a discharge-weighted concentration of about 50 mg l^{-1} .

If we assume that our measurement of 235 mg l^{-1} represents the discharge-weighted concentration of suspended sediment at high discharge at Óbidos and that Ames' measurement of 50 mg l^{-1} represents the concentration at low discharge, and if we assume that the relationship between mean monthly discharge and mean monthly concentration follows the power relation plotted in Fig. 3b, we can compute monthly sediment loads for the average monthly discharges shown in Fig. 3a, and we can sum the monthly loads to obtain an estimate of the mean annual load of suspended sediment at Óbidos. This procedure gives an estimate of $9.3 \times 10^8 \text{ tonnes yr}^{-1}$. A slightly more conservative estimate can be computed if we assume that the mean concentration in the month of highest discharge is only 200 mg l^{-1} and that the concentrations in the other months range correspondingly between this value and the minimum

Table 1 Suspended-sediment loads measured in Amazon River and its tributaries, 1977

Location	Date	Water discharge ($\text{m}^3 \text{s}^{-1}$)	Suspended sediment	
			Concentration (mg l^{-1})	Load ($10^6 \text{ tonnes d}^{-1}$)
Iquitos	20 May	48,000	400	1.7
São Paulo de Olivença	22 May	70,000	275	1.7
Santo Antônio do Iça	23 May	80,000	245	1.7
Itapeúa (Coari)	26 May	110,000	150	1.4
Manacapuru	27 May	130,000	200	2.2
Rio Negro	28 May	50,000*	5	0.02
Rio Madeira	1 June	40,000	330	1.1
Óbidos	2 June	230,000	235	4.7

* Estimated by subtracting from discharge at Óbidos ($230,000 \text{ m}^3 \text{s}^{-1}$) the following: discharge of mainstem at Manacapuru (130,000), estimated discharge of Rio Madeira at Novo Aripuanã (40,000), and estimated discharge of Rio Trombetas (5,000) and other tributaries (5,000) between Manacapuru and Óbidos.

concentration of 50 mg l^{-1} ; in this case, the estimated annual suspended-sediment load at Óbidos is $8.2 \times 10^8 \text{ tonnes yr}^{-1}$.

How much of this sediment is discharged onto the continental shelf at the mouth of the river? Óbidos is about 850 km (river distance) above the mouth of the Amazon. The tributaries that enter the river below Óbidos add another 10% to the water discharge but do not add any significant amount of sediment. The question centres on how much of the sediment is deposited on the wide alluvial plain and in the extensive delta that lie between Óbidos and the sea. Even if this amount is substantial—as much as 20% of the sediment that passes Óbidos, for example—the remaining sediment load would place the Amazon behind only the Yellow River of China and the Ganges-Brahmaputra system of India and Pakistan as a supplier of sediment to the oceans⁴.

We thank the following for assistance in constructing the sampling equipment, obtaining the data, and reviewing the manuscript: F. C. Ames, J. P. Beverage, R. F. Hadley, D. W. Hubbell, G. A. Lutz, H. A. Mahoney, J. V. Skinner, and H. H. Stevens of the USGS; officers and crew of RV Alpha Helix, which is operated by Scripps Institution of Oceanography and funded by the NSF; theodolite crews of CPRM and Hidrologia S.A.; Barry Grant of MIT; Cdr. M. Perez of Marinha do Brasil; N. J. Bóio and P. M. B. Landim of Universidade Estadual Paulista, Rio Claro; Nelson da Franca Ribeiro dos Anjos of ELETROBRÁS; Marcello Bezerra and Sylvio Cristino da Conceição of CPRM; Stelio da Silva Elleres de Sousa of DNAEE.

Note that the greatest monthly mean flow for the 4-yr period is only 3 times the smallest. b, Assumed relation between mean monthly concentration of suspended sediment and mean monthly river discharge at Óbidos.

Photolysis of highly chlorinated dibenzo-*p*-dioxins by sunlight

CHLORINATED dibenzo-*p*-dioxins (CDDs) are now widely recognised as contaminants of commercial chlorinated phenols and related products. These compounds possess a remarkable range of toxicity; the LD_{50} for 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (2,3,7,8-TCDD) in female rats is $45 \mu\text{g per kg}$, that of the octachloro compound (OCDD) is $> 1 \text{ g per kg}$ (ref. 1). Although the degree of toxicity is related to the extent of chlorination, positional isomerisation also plays a critical and perhaps dominant part, 1,2,3,4-TCDD is at least 800 times less toxic than 2,3,7,8-TCDD (ref. 2). The extreme toxicity of some of these compounds, coupled with the large variations with extent of chlorination and positional isomerisation, make accurate

Fig. 1 Photolysis of OCDD in hexane. The rate constants and half lives quoted here derive from an experiment involving consecutive daily exposures of samples in hexane solution contained in matched quartz photolysis cells. The samples were exposed from 09.00 to 15.00 in late September/early October 1977 at Princes Risborough. The kinetics were all found to be first-order when the total time exposed was used (minimum correlation coefficient 0.986 for 10 data points). Hours of direct sunlight did not produce such a good correlation. The experiments have been repeated outside at other times of the year and in the laboratory and once allowance is made for the different incident light intensities the results are in agreement. For example, the half lives of OCDD were found to be 7.0 h at the beginning of August and 9.0 h in mid September. The computed ratios of the rate of OCDD destruction to the rate of conversion of OCDD to HpCDD(2H) are, however, independent of the solar intensity and the same results have been found in laboratory experiments using a fluorescent blacklight for the photolyses. In all cases the concentrations of the solutions used were such that less than 10% of the incident light was absorbed.

identification of CDDs essential in any assessment of environmental or safety implications. The study reported here is concerned with the photolysis of octa-, hepta (Hp)- and some hexa (Hx)-chlorodibenzo-*p*-dioxins and shows that the structural isomers which are expected to be the most toxic are most rapidly photodecomposed. We also report that despite photolytic reductive dechlorination which gives rise to less highly chlorinated dioxins, the reaction mechanism favours the formation of the less toxic isomers.

OCDD is a common contaminant of the widely used biocide pentachlorophenol occurring at a concentration of $\sim 1,000 \mu\text{g}$ per g in the commercial product³. Previous work has shown that photolytic reductive dechlorination can occur^{4,5} and the possible safety implications of this have been considered⁵ but without any detailed consideration of the kinetics or the mechanism of reaction.

Figures 1 and 2 summarise the principal results of our work which, although designed to study the photolysis of OCDD, has also provided data of relevance to other CDDs. The first photolysis experiments, conducted with a solution of OCDD in hexane (approximately $1 \mu\text{g}$ per ml) containing traces of HpCDD isomers, indicated that the OCDD and one of the HpCDD isomers were photolytically decomposed but that the other HpCDD increased in concentration during photolysis. Figure 3 shows gas chromatography (GC) traces illustrating this behaviour. There was also evidence from the GC traces of an increase in concentration of another compound which has a relative retention time on GC in the region expected for a HxCDD⁶. As photolysis continued, and the concentration of OCDD decreased, the concentration of the HpCDD isomer that had previously increased reached a steady state and then decreased. The same behaviour was found when the initial ratios of concentrations of HpCDD and OCDD were changed. The HpCDD is therefore generated by photolysis of OCDD. Photolytically-induced reductive dechlorinations have been reported before for chlorinated dioxins^{4,5} but the identification of the formation of a specific HpCDD facilitates an investigation of the mechanism of reaction.

Highly chlorinated dibenzo-*p*-dioxins can be formed by controlled heating of sodium chlorophenoxides⁶. We prepared OCDD from purified sodium pentachlorophenoxide and confirmed the structure by mass spectroscopy. Other CDD compounds cannot be prepared in the pure state in this way. HpCDD and HxCDD were prepared by the controlled heating of mixtures of sodium pentachlorophenoxide and specific sodium tetrachlorophenoxides^{6,7} and we confirmed their identity by GC analyses on QF-1 and OV-101 columns. The relative retention times with respect to OCDD on OV-101 were in agreement with published values⁸.

Comparison of the GC traces from the photolysed solution on two GC columns with samples of authentic compounds prepared as above showed that the HpCDD which increased in concentration was the 1,2,3,4,6,7,9-HpCDD (or HpCDD(2H)). Similarly, the peak in the HxCDD region could be assigned to the 1,2,4,6,7,9-HxCDD (or HxCDD(2,7H)).

To study the kinetics of photolytic degradation of both the HpCDDs, we minimised the formation of HpCDD from OCDD by varying the ratios of sodium penta- and tetrachlorophenoxides used in the synthesis of CDDs. The ratio of concentrations of HpCDD and OCDD chosen was at least 20 times the concentration ratio at which the photolytic production and destruction of HpCDD(2H) were found to be equal. These solutions also contained HxCDD isomers and the half lives for these compounds in sunlight are shown in Fig. 2.

All the solutions were exposed in matched quartz photolysis cells placed in a rack so that each solution was exposed to the same intensity and spectrum of sunlight. The rate constant for conversion of OCDD to HpCDD(2H) in these conditions (Fig. 1) can be calculated from the ratio of concentrations of these two compounds at the photostationary state for HpCDD(2H). As no ratio of concentrations was found for which the concentration of HpCDD(1H) increased during photolysis, only an upper limit to the rate can be calculated.

It is clear from Fig. 1 that OCDD is short lived when exposed to sunlight in hexane solution. From the rate constants we deduce that reductive dechlorination to produce less chlorinated dioxins is a minor photolytic pathway accounting for $< 10\%$ of the OCDD destroyed. The GC traces showed the photolytic formation of compounds with retention times longer than that for OCDD: these compounds are not simple CDDs and have not been identified.

There are two groups of chlorine atoms in OCDD: those bonded to carbon atoms in the 1-position, which are adjacent to an oxygen substituent (1,4,6 and 9 in Fig. 1) and those bonded to carbon atoms in the 2-position (2,3,7 and 8 in Fig. 1). The half lives (Figs. 1 and 2) indicate that CDDs with chlorine atoms in the 2-position photolyse more rapidly than those with chlorine atoms in the 1-position. This seems to be due partly to the

Fig. 2 Photolytic half lives for various hexachlorodibenzo-*p*-dioxin isomers exposed to sunlight in hexane solution in the same conditions as the solutions used for Fig. 1. The solution containing HxCDD(1,9H) also contained some HxCDD(1,6H) which is produced on heating sodium 2,3,4,6-tetrachlorophenoxide^{6,7}. The GC procedure used for the kinetics did not resolve these isomers, initially present in a ratio of $\sim 1:3$, HxCDD(1,6H):HxCDD(1,9H). The decay of the composite peak followed first-order kinetics for a period of over five half lives; as the major component of the peak was the HxCDD(1,9H) the half life found is ascribed to this compound. The half life of the HxCDD(1,6H) must be very similar to the HxCDD(1,9H), otherwise the decay of the composite peak would have been more complex.

Fig. 3 GC traces from a hexane solution of approximately $4 \mu\text{g ml}^{-1}$ OCDD containing traces of HpCDD impurities before (a) and after (b) exposure of the solution in a quartz photolysis cell to sunlight. The peak labelled DCB is from decachlorobiphenyl ($0.05 \mu\text{g ml}^{-1}$) used as an internal standard for the GC analyses. These chromatograms were run on a Pye 104 gas chromatograph using EC detection. A 1-m column packed with 5% QF-1 on Diatomite C-AW-DCMS 80–100 mesh was used with a column temperature 210°C , detector temperature 300°C and nitrogen gas flow rate 120 ml min^{-1} . Analyses were also carried out with a 1-m column containing 3% OV-101 on Chromosorb W-HP 100–120 mesh, operated with the same temperatures as for the QF-1 column and a nitrogen gas flow rate of $\sim 50 \text{ ml min}^{-1}$. The concentration of OCDD in solutions was found by comparison with standard solutions and approximate HpCDD concentrations found by comparison of peak areas of HpCDD peaks with those for OCDD with allowance for the relative ECD responses of the compounds⁸. Decay constants were found by comparison of photolysed samples with diluted solutions of the unphotolysed solution. The relative retention times for the compounds of interest are:

Compound	Relative retention times		Literature values OV-101 (ref. 8)
	QF-1	OV-101	
OCDD	1.00	1.00	1.00
HpCDD(1H)	0.62	0.59	0.58
HpCDD(2H)	0.57	0.53	0.52
HxCDD(1,6H)	0.39	0.34	0.34
HxCDD(1,7H)	0.36	0.31	0.31
HxCDD(1,9H)	0.44	0.36	0.36
HxCDD(2,7H)	0.32	0.28	0.27
Decachlorobiphenyl	0.42	0.51	—

greater reactivity of the 2-position chlorines, shown by the higher rate of formation of HpCDD(2H) than HpCDD(1H). However, other factors are also involved because compounds possessing the same number of chlorine atoms in the 2-positions photolyse more rapidly as chlorine atoms are removed from the 1-positions ($t_1\{\text{HxCDD}(1,9\text{H})\} < t_1\{\text{HpCDD}(1\text{H})\}$) and $t_1\{\text{HxCDD}(1,7\text{H})\} < t_1\{\text{HpCDD}(2\text{H})\}$). Extrapolation of these results leads to the prediction that 2,3,7,8-TCDD should be the most photolabile of the chlorinated dibenzo-*p*-dioxins.

Available evidence on CDDs^{1,2}, and the similarities between the behaviour of the CDDs and other compounds with similar molecular shapes⁹, suggest that the presence of chlorine atoms in the 2,3,7 and 8 positions is critical for toxic effects (enzyme inhibition studies suggest at least three chlorine atoms¹⁰). The observations we report are therefore reassuring from the environmental point of view as the molecules that are likely to be the most toxic are the most susceptible to photodegradation, and the photodegradation of highly chlorinated dibenzo-*p*-

dioxins is not a facile route for the generation of the highly toxic, less chlorinated compounds.

We thank Dr Woolley, Fire Research Station, BRE for carrying out the mass spectroscopy. This work was carried out as part of the research programme of the Building Research Establishment of the Department of the Environment and is contributed by permission of the Director.

The evolution of the cell-cell recognition system

THE invention of sexuality was one of the milestones in the evolution of organisms. Indeed, in both unicellular and multicellular organisms, sexuality, by allowing the exchange of genetic material between cells, has been the major driving force of evolution. On the other hand, sexuality requires surface structures for the specific recognition and mating of the cells of the two gametic types. One of us (A.M.) has recently suggested that the cell-cell recognition system is phylogenetically linked to the appearance of sexuality¹. A phylogenetic connection between sexuality and cell recognition has also been suggested by Bennett *et al.*². Here, we will elaborate on this idea.

We can only speculate on the organisation of the cell membrane in the primitive prokaryotes; it may have been just a lipid bilayer. The major advance in this organisation must have been the insertion of proteins and/or glycoproteins in the bilayer. This step provided the cell membrane with an immense potential for modulating its molecular organisation; and this may have been the basis for the species-specific organisation of the cell membrane and hence of cell recognition. We do not know this happened concurrently with the appearance of the sexuality factors; in any case, it may be assumed that the sexuality factors were responsible for encoding certain proteins which became inserted into the membrane of the cells carrying such factor(s).

Jacob *et al.*³ have suggested that in bacteria, conjugation depends on an antigen, the F-antigen, at the bacterial surface of the F⁺ of *Hfr* males, which 'would allow the host to recognise cells which do not carry the episome and to conjugate with such cells'. Hence, originally the mating reaction would have resulted from the interaction between surface components specific for the (+) cells (which in *Escherichia coli* seem to be located at the tip of the F-pilus⁴) with some surface component of the (–) cells. Indeed, one might visualise a situation in which the molecules encoded by the sex factor(s) at the surface of the (+) cells were similar to lectins or multivalent antibodies and interacted with some of the glycoprotein components of the surface of the (–) cells in a process similar to 'anchorage modulation' or cap

formation⁵. The suggestion of Jacob *et al.* is supported by recent work of Kennedy *et al.*⁶ which shows that the proteins coded for by the *tra* operon (the transcriptional unit containing the genes required for the synthesis of the F-pili and the stabilisation of the mating aggregates, for DNA transfer and for surface exclusion which prevents the interaction of F cells with other donors) are associated with the cell envelope. The fact that the *tra* operon also codes for a membrane protein (PTraT, which is responsible for surface exclusion)⁷ is particularly important in connection with the origin of the specificity of cell-cell recognition and interaction. It is worth mentioning at this point that the incompatibility system in higher plants also depends on proteins at the surface of the pollen tube whose synthesis is controlled by the S locus (see ref. 8 for review).

Apparently, very early in the course of evolution not only did the molecular organisation of the cell surface fall under genetic control, but also the surface structures involved in conjugation were, in turn, able to control the activity of the genetic apparatus. The observations of Skurray and Reeves⁹ are an example of this. These authors found that in the F⁻ cells certain functions, notably DNA synthesis, are inhibited during conjugation. On the other hand, the location on the bacterial membrane of the initiator site of DNA replication³ is well known. The next step in the evolution of recognition in the mating reaction in lower eukaryotes must have been the establishment of specificity of the 'molecular fit' of the receptor sites. For example, in the yeast *Hansenula wingei* it has been shown that mating results from the interaction of two glycoproteins at the surface of the cells of the two mating types¹⁰⁻¹². In *Clamydomonas*¹³, the putative area of fusion between mt⁺ and mt⁻ cells seems to be a structurally specialised area of the cell surface which differentiates during gamete maturation. However, precise knowledge of the molecular composition and organisation of the receptor sites is still lacking.

We suggest that the cell-cell communication system has evolved from the membrane structures originally meant for cell recognition in the mating process. In this connection, we can cite the experiments of Miyake (see his review, ref. 14) on the ciliate *Blepharisma*. In this organism, the preconjunction events of cell interaction between mating types I and II are mediated by two 'gamones' (gamones 1 and 2) secreted by the cells. Both gamones are able to induce cell union events between cells of the same mating type. In this case, however, the union remains sterile, that is, none of the nuclear events—meiosis, exchange and fusion of gametic nuclei—that occur when cells of the two different mating types unite, will follow. By taking advantage of a mutant, *doublet*, which is provided with two sets of oral openings (cell union occurs in the oral region), chains of cells of the same mating type could be constructed by submitting them to the action of gamone 1. If at this point one singlet (that is, of the wild type with one oral opening) cell of the complementary mating type (pretreated with gamone 2) is attached to one end of such a chain, the conjugation events are immediately activated in a chain-like sequences, that is, they start on the cell closest to the 'inducer' cell and propagate from cell to cell.

Let us now leap from the unicellular to the multicellular organisms. We suggest that this event in evolution was concurrent with the segregation of the somatic from the germ cell line. The dichotomy between the two cell lines involves (1) in the somatic cell line, the silencing of the genetic apparatus coding for the surface structures responsible for the recognition between male and female individuals; (2) in the germ line, the retention of a fully (or at least largely) derepressed genome.

According to this hypothesis the cells of the germ cell line have retained their ancestral surface organisation whereby only cells belonging to the opposite sex can interact with one another. In this connection it may be significant that in vertebrates the primordial germ cells originate far away from the gonadal ridge and migrate as single cells.

On the other hand, although the matter has not been investigated with this question in mind, the formation of mouse chimaeras¹⁵⁻¹⁷ shows that genetically male and female embry-

onic cells do not discriminate between one another. Also, hybrid histotypic aggregates can be formed in culture from such species as far apart as chick and mouse¹⁸⁻²⁰. (However, we must remember that *in vitro* conditions may alter the organisation of the cell surface in such a way that some properties such as the species specificity are lost, while the tissue specificity is retained.) These experiments suggest that the structures discriminating between male and female are not expressed at the surface of these cells.

The retention of a largely derepressed genome by the cells of the germ line is inferred from the fact that in the oocyte, the complexity of the transcripts is several times greater than in the somatic cells (see, for example, ref. 21). Although we know of no such direct evidence in the case of the male germ cells, it has been shown that at least in *Drosophila*, spermatocytes exhibit lampbrush chromosomes comparable to those of the oocyte²².

It is therefore not surprising to find at the surface of the germ cells—both eggs and spermatozoa—antigens and other molecules which are also present at the surface of highly specialised somatic cells. One such example is the presence of acetylcholine receptors at the surface of the *Xenopus*²³ and of the mouse oocyte²⁴. The role of these receptors is obscure; in the mouse oocyte they are no longer detectable in the two-cell embryo²⁴.

Finally, we should mention the relevance here of some of the information now available on the T locus in the mouse. Indeed, it has been shown that mutations at this locus result in both segregation distortions in males and fertility alterations²⁵ and that they also affect cell interactions during the early stages of embryonic development. The antigens encoded by the T locus are expressed at the surface of the spermatozoon but not of any somatic cell, thus suggesting that they may have an important role in gamete differentiation and during early embryonic development²⁶. The location on the same chromosome (and in very close proximity to each other) of the T locus and the H-2 locus which specifies the major histocompatibility antigens may also suggest an evolutionary relationship between the genetic system controlling gamete differentiation, cell recognition and the immune system of the higher vertebrates.

We thank Drs G. Bernardi, J. Brachet, R. Miledi, A. A. Moscona and R. Nobili for reading the manuscript and for their comments.

Microtubules, cell wall deposition and the determination of plant cell shape

THE shape of plant cells depends largely on the orientation of cellulose microfibrils in their cell walls¹. In almost all cells where the microfibrils are regularly arranged, cortical microtubules lie parallel to the wall microfibrils. Experimental evidence indicates that these microtubules influence the arrangement of the deposition of wall microfibrils². How microtubules determine the orientation of microfibrillar deposition is not yet known^{3,4}, but it has been speculated that they may influence the alignment of cellulose synthetase enzymes on the plasma membrane⁵. Microtubules act as a cytoskeleton in the formation and maintenance of cell shape in many types of cells⁶ including plant cells which lack a cell wall⁷, or before a wall is deposited⁸, and it may be that microtubules, in those plant cells where they are arranged congruently with recently deposited wall microfibrils, directly determine cell shape. However, using coumarin to inhibit cell wall regeneration by protoplasts of *Mougeotia* I demonstrate here the inability of microtubules to directly determine cell shape.

Spherical protoplasts of this freshwater alga, isolated following enzymatic digestion of its cell wall, readily regenerate a new wall and revert to their original cylindrical cell shape⁹. The ratio of length to diameter (axial ratio) of these cells is very large, making them ideal for investigations on the mechanisms controlling the development of cell asymmetry. Following attachment to a substratum, these protoplasts can be burst by osmotic shock to reveal the cytoplasmic face of the plasma membrane and microtubules associated with it¹⁰. Cortical microtubules become linked by cross bridges to the membrane during the first 3 h of protoplast culture (unpublished data). Intact protoplasts treated with 0.2% colchicine or 10^{-4} M isopropyl *n*-phenylcarbamate (IPC) lose their cortical microtubules¹⁰ and regenerate a cell wall in which the microfibrils are randomly orientated. These cells remain spherical (unpublished data).

Coumarin (1,2-benzopyrone) inhibits the biosynthesis of cell wall components, especially cellulose¹¹, and prevents the deposition of microfibrils on the surface of regenerating tobacco

leaf protoplasts¹². This drug does not affect the cortical microtubules of plant cells¹³. Freshly isolated protoplasts of *Mougeotia* were washed in protoplast maintenance medium (PMM), which contains 0.2 M mannitol, 0.2 M sorbitol, 2 mM $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ and 2 mM NaH_2PO_4 at pH 5.5. A stock solution of 50 mg ml⁻¹ coumarin (Sigma) in ethanol was diluted with PMM to 250 $\mu\text{g ml}^{-1}$. Protoplasts were incubated in this solution at 20 °C on the same 16/8 h light/dark regime they had experienced before removal of their cell wall. Control protoplasts were maintained in PMM containing 0.5% ethanol. Wall regeneration by the protoplasts was monitored by staining with 0.1% Calcofluor M2R New (American Cyanamid), a fluorescent stain for β -polysaccharides¹⁴, as well as by transmission electron microscopy.

Fig. 2 *a*, Transmission electron micrograph of part of a *Mougeotia* protoplast plasma membrane. Protoplasts were allowed to settle on formvar/carbon-coated grids treated with poly-L-lysine. They were then burst by osmotic shock in a microtubule stabilising buffer containing 1 mM MgSO_4 , 2 mM EGTA and 100 mM PIPES at pH 6.9 and negatively stained with uranyl acetate. This protoplast had been incubated in 250 $\mu\text{g ml}^{-1}$ coumarin for 24 h before bursting. Microtubules are conspicuous on the membrane. Scale marker = 1 μm . *b*, High magnification micrograph of the plasma membrane of a burst coumarin-treated protoplast showing microtubules. Scale marker = 0.5 μm .

Fig. 1 *a*, Photomicrograph of a protoplast of *Mougeotia* that has been cultured in 250 $\mu\text{g ml}^{-1}$ coumarin in PMM for 24 h; it lacks a cell wall and remains spherical. Scale marker = 10 μm . *b*, Normal regeneration of a *Mougeotia* protoplast after 24 h in PMM without coumarin. The cell has a wall and is ovoid in shape. Scale marker = 10 μm .

Over 50% of untreated protoplasts regenerate a cell wall after 5 h in culture, and by 24 h over 90% have a wall. Such regenerating cells become ovoid after about 12 h, cylindrical within 2 d, and by the third day of culture many have divided⁹. Protoplasts treated with coumarin for up to 3 d do not develop a cell wall that is detectable by electron microscopy or by Calcofluor fluorescence, and they remain spherical (Fig. 1). These protoplasts could be ruptured by osmotic shock (further evidence for their lack of a cell wall) and contain microtubules attached to the plasma membrane (Fig. 2). The cortical microtubular arrays are indistinguishable from those in untreated cells. If coumarin-treated protoplasts were transferred to PMM lacking coumarin they develop a cell wall and become cylindrical; the time course of this belated development is similar to that of the controls.

If coumarin does not affect microtubules, as suggested by this work and that of Itoh¹³, they apparently have no direct cytoskeletal function in developing the shape of these cells as they do in *Ochromonas*⁷, *Pediastrum*¹⁵ and some higher plants¹⁶. The finding that coumarin-treated protoplasts do not deposit a cell wall and that they remain spherical clearly implies that the wall is necessary for establishing cell shape as well as for its maintenance. Experiments with colchicine and IPC suggest that, as in

higher plants, cortical microtubules control cell shape by influencing the pattern of microfibril deposition.

Non-selective isolation of human somatic cell hybrids by unit-gravity sedimentation

DATA from somatic cell hybridisation have made important contributions to the understanding of genetic control of phenotypic expression, the nature of malignancy in tumours, gene mapping and the basic genetic lesions causing metabolic diseases^{1–5}. Broader application has been limited by the absence of biochemical markers in most cell strains and lines, making it difficult to eliminate parental cells and isolate hybrids. Recent non-selective methods of isolating hybrid cells require either expensive and elaborate equipment⁶ or examination of large numbers of clones with a low yield of hybrids⁷. We now present a method for isolating tetraploid clones from fused human fibroblasts non-selectively and in high yield. Our technique is applicable to tetraploid cells formed from any pair of diploid cells as long as the synkaryons so formed can proliferate. The method depends on the separation of fused cells from the unfused parental cells because of their greater size. A mixture of cells settles out according to size in a shallow bovine serum albumin (BSA) gradient at unit gravity, yielding fractions enriched in double-nucleated cells from which tetraploid clones can be isolated in high yield.

Our goal was to fuse human fibroblasts with polyethylene glycol and then fractionate them by means of a 'staput' chamber⁸. A thin layer of fused cell suspension was pipetted on top of a shallow gradient solution in the chamber and left to settle at unit gravity. In these conditions, sedimentation velocity was almost directly proportional to the square of the cell radius⁸, so that the larger fused cells settled out faster than the smaller unfused cells. After the specific time for differential sedimentation had elapsed, cell fractions were collected from the bottom of the gradient.

To keep the fibroblasts in a monodispersed state for effective separation and to maintain their maximal viability for cloning, we found that BSA dissolved in otherwise serum-free culture medium (Ham's F-10) was superior to Ficoll or fetal calf serum as the gradient material. Because the purpose of the gradient was to prevent adjacent layers from mixing during collection, the percentage of BSA in the gradient could be varied, for

example, from 1 to 3%, without affecting the separation significantly. Addition of anti-clumping agents such as 12 mM xylocaine or 0.01% EDTA⁹, although reducing clumping to a minimum, also reduced cell viability by up to 40%. Substitution of phosphate-buffered saline (PBS) for culture medium led to slightly increased clumping, and the presence of fetal calf serum in either the culture medium or PBS caused marked clumping of the fibroblasts.

Fig. 1 Sedimentation profiles of unsynchronised fibroblasts and fibroblasts synchronised by serum starvation. Approximately 5×10^6 human skin fibroblasts cultured in Ham's F-10 medium supplemented with 20% fetal calf serum, glutamine and antibiotics, or a similar number of fibroblasts synchronised by serum starvation (0.2% of fetal calf serum in Ham's F-10 medium for 3 d) were collected with trypsin (0.125%) and EDTA (0.02%). Cells were suspended in 20 ml of Ham's F-10 medium and layered as a thin band on top of a gradient of 2–3% bovine serum albumin in Ham's F-10 medium in the staput apparatus with a 10-ml pipette. After sedimentation at 4 °C for 3 h, 50-ml fractions were collected from the bottom of the gradient. Each fraction was centrifuged at 200g for 10 min, and the pellets were suspended in 0.5 ml of complete medium for cell counts. ○, Unsynchronised fibroblasts; ●, fibroblasts synchronised by serum starvation.

A further complication with cultured fibroblasts was the variability in size among the diploid parental cells, in part due to their being in different phases of the cell cycle. To bring them to a homogeneous size range before fusion and thus maximise the size difference between the fused and unfused cells after fusion, techniques known to induce cell synchrony were tried. We found that serum starvation reduced considerably the variation in cell size (Fig. 1), so that the width of distribution at half peak height was 2.4 units (B) for the serum-starved population compared to 4.1 units (A) for the untreated cells. Thus by this treatment fewer larger cells and a predominance of smaller cells were obtained. Synchronisation by leaving cells to grow to confluence, or by single or double thymidine block was less successful than serum starvation in reducing the variation of cell size, and furthermore, thymidine treatment tended to increase clumping.

After synchronising human skin fibroblast strains by serum starvation, we fused two strains with polyethylene glycol 1000 (ref. 10) and fractionated the cells according to size in the staput chamber containing a gradient of 2–3% BSA dissolved in serum-free Ham's F-10 culture medium (Fig. 2). Because cells with more than two nuclei do not divide¹¹, they could be ignored for subsequent cloning purposes. However, fractions that contained the highest ratio of double-nucleated cells to single-nucleated cells should have the best chance of yielding tetraploid clones. Therefore, the earliest fractions (1–8) collected from the bottom of the sedimentation chamber with an average ratio of double-nucleated to single-nucleated cells of 2:1 were used for cloning. In contrast, the original unsorted sample had an average ratio of 0.17:1.

Of the 72 clones successfully propagated for identification by karyotyping¹², 18 (25%) had a modal number of 46 (diploid), nine (12.5%) had both diploid and tetraploid cells and 45 (62.5%) were tetraploid. Several tetraploid clones were carried through multiple passages, each maintaining their complement of 92 chromosomes.

Vigorous growth capability in both parent cell strains was essential for successful propagation of tetraploid clones. For example, when we fused a female skin fibroblast strain with a male skin fibroblast strain that was much more vigorous in growth, we found that of the 45 tetraploid clones, at least 24 were apparently from male-male fusions with two Y chromosomes. Only nine clones were judged to be from female-female fusions, as shown by the absence of a Y chromosome, and 10 were judged to be from male-female fusions, as shown by the presence of only one Y chromosome. The identification of the last two categories was tentative, as the complete tetraploid chromosome number of 92 was seldom obtained. The number of chromosomes counted was most often approximately 80, mainly because of the technical difficulty in spreading so many chromosomes properly for counting and identification.

To overcome this difficulty of identifying true hybrids cytogenetically, we used the isozymes of glucose-6-phosphate dehydrogenase (G6PD) as markers^{13,14}. A fibroblast strain with the G6PD_A isozyme was fused with another strain with the G6PD_B form. After separation in the staput chamber, clones propagated from fractions 1–8 were identified cytogenetically as diploid or tetraploid. All the tetraploid clones were then subjected to electrophoresis to identify their G6PD profile. Tetraploids formed from homologous fusion between the same parent cell types would show either the A or the B form. Hybrid tetraploids formed from heterologous fusion between the two parent cell types would show the hybrid heteropolymer between the A and B form in the ratio of 1:2:1. Out of 202 clones isolated from fractions 1–8, 114 were growing sufficiently vigorously for karyotyping. Of these, 31 were tetraploid, seven were mixed tetraploid and diploid and 76 were diploid. Electrophoretic separation of G6PD isozymes in 30 of the tetraploid clones showed that six had the typical hybrid pattern, 21 had only the A form, one had the appearance of the hybrid form mixed with the A form, 1 had the B form and one had both A and B. Thus, of the 30 clones judged to be tetraploids, 20% were found to be pure hybrid clones.

We have thus shown that by exploiting the different sizes of hybrid cells and their unfused parents, hybrid tetraploid clones can be obtained in high yield. The staput apparatus provides a relatively simple technique for separating somatic cell hybrids and is applicable to a wide variety of cell types which have not been studied previously because of their lack of biochemical selection markers. Furthermore, because hybrid clones can be isolated without perturbing the genetic composition of the parental cell strains by chemical or physical selection, the exact biochemical and genetic mechanisms that account for complementation between some types of inborn error of metabolism may be more easily revealed and questions of gene dosage and gene inactivation can be examined in the hybrid clones without constraint.

Financial support from the MRC, Canada (MA-5789), technical assistance from M. Gedeon, A. Davidson and Dr N. Rosa and advice in karyotyping from Dr I. Uchida and her staff are gratefully acknowledged. The G6PD_A cell strain was provided

Fig. 2 Separation of human skin fibroblasts by unit-gravity sedimentation in the staput apparatus after fusion with polyethylene glycol. Fibroblasts synchronised by serum starvation were seeded in T-75 culture flasks (Corning) at a density of 4×10^6 cells per flask (2×10^6 cells from each of two fibroblast cell strains) and incubated for 24 h in complete medium (Ham's F-10 supplemented with 20% fetal calf serum). They were fused with polyethylene glycol 1000 according to the procedure of Davidson *et al.*¹⁰ and incubated for about 16 h before collection for separation in the staput apparatus, as described in the legend to Fig. 1. After sedimentation at 4 °C for 4 h, 50-ml fractions were collected from the bottom and centrifuged at 200g for 10 min. The pellet was suspended in 0.5 ml of complete medium for cell count, Giemsa staining and cloning. The entire operation was performed in sterile conditions. —, No. of cells per fraction; S, sample cell load before sedimentation. Open columns, one nucleus per cell; solid columns, two nuclei per cell; hatched columns, more than two nuclei per cell.

by Dr B. R. Migeon. Assistance from Drs H. Teh and R. Phillips with the pilot staput experiments and the critical reviews of the manuscript by Drs S. Goldstein and A. Peterson are also appreciated.

Infection of the Mongolian gerbil with the cattle piroplasm *Babesia divergens*

DISEASES of cattle caused by piroplasms are one of the major constraints on the growth of the livestock industry in the tropics. *Babesia divergens*, which is the common cause of redwater in European cattle, can be transmitted to splenectomised goats, sheep and deer by the inoculation of blood from infected cattle¹. Furthermore, it has been shown experimentally that *B. divergens* is transmissible in this way to chimpanzees². Evidence is now accumulating to suggest that it is this species of *Babesia* which is capable of causing fatalities in splenectomised humans in Europe^{3,4}. Our inability to adapt cattle piroplasms to small laboratory animals has restricted efforts to develop new drugs

Table 1 *B. divergens* parasitaemias of infected gerbils up to 96 h post-inoculation

Time post-inoculation (h)	No. of infected erythrocytes per 1,000			
	G1	G2	G3	G4
24	<1	<1	<1	<1
48	<1	<1	<1	<1
72	58	17	7	7
96	372	50	236	67

G1 and G2 were splenectomised gerbils; G3 and G4 were intact gerbils.

Table 2 Summarised reactions of splenectomised Friesian calves to the inoculation of approximately 10^8 *B. divergens*-infected erythrocytes

Calf no.	No. of infected erythrocytes inoculated	Origin of parasites inoculated	Parasitaemia		Febrile response		Haematology	
			Prepatent period to parasitaemia of 1 per 1,000 RBC (d)	Maximum parasitaemia per 1,000 RBC	Prepatent period to febrile response of $\geq 39.5^\circ\text{C}$ (d)	Maximum febrile response ($^\circ\text{C}$)	Lowest PCV (%)	Highest MCV (μm^3)

and vaccines against them. However, during a recent investigation of a human fatality⁵, we were able to transmit the parasite to gerbils by inoculation of infected blood from the patient. Although final evidence to implicate *B. divergens* in this instance is still being assessed, we decided to investigate the possibility of infecting gerbils with *B. divergens*-infected blood from cattle. We now report the successful adaptation of *B. divergens* to the Mongolian gerbil (*Meriones unguiculatus*).

A splenectomised Friesian calf reacting to inoculation with a strain of *B. divergens* originally isolated from Eire had a *B. divergens* parasitaemia of 61 infected erythrocytes per 1,000 cells. A sample of 75 ml of blood was taken from the calf's jugular vein into Anticlot (Clinton Laboratories) and centrifuged at 3,400g for 20 min. The resultant pellet was resuspended and washed three times in phosphate-buffered saline (PBS) (pH 7.2). The pellet was finally reconstituted so that 0.7 ml contained $\sim 5 \times 10^8$ *B. divergens*-infected erythrocytes.

Four gerbils, two intact and two splenectomised, were each inoculated intraperitoneally with 0.7 ml of the reconstituted blood. Thin blood smears were made daily from the gerbils' tail-tips and stained with Giemsa. Parasites were seen in blood smears from all animals from day 1 post-inoculation and parasitaemias are shown in Table 1. Parasites present in the blood of infected gerbils exhibited considerable pleomorphism (Fig. 1*a*); however, several of these forms were characteristic of *B. divergens* piroplasms in infected bovine erythrocytes (see Fig. 1*b*).

On day 4 post-infection all the gerbils had significant *B. divergens* parasitaemias. One intact animal with a 23% infection of *B. divergens* piroplasms was killed and 0.1 ml of blood containing 2×10^7 infected erythrocytes was inoculated intraperitoneally into two further gerbils (G5 and G6). On the fourth day after inoculation gerbil G5 had a parasitaemia of 14 infected erythrocytes per 1,000 and a red blood cell (RBC) count of 8.9×10^9 per ml; gerbil G6 had a parasitaemia of 59 per 1,000 erythrocytes and an RBC of 6.2×10^9 per ml. They were killed and ~ 1.5 ml of blood was recovered from each animal, representing 1.8×10^8 and 5.5×10^8 *B. divergens*-infected erythrocytes, respectively. The erythrocytes were washed and

resuspended in PBS as before. Splenectomised calf M1010 was then inoculated intravenously with parasites from gerbil G5 and splenectomised calf M1011 with parasites from gerbil G6. A further 0.2 ml of blood from each infected gerbil was inoculated into a splenectomised control gerbil. Both control gerbils subsequently experienced similar reactions to those of the animals used in the first passage of bovine blood.

The reactions of the two splenectomised calves and that of a splenectomised control calf inoculated with 9.7×10^7 *B. divergens* parasites (Eire strain) are summarised in Table 2.

We have thus demonstrated (1) that gerbils can be infected with *B. divergens* by the intraperitoneal inoculation of infected bovine blood; (2) that the parasite is then transmissible to further gerbils; (3) that the parasite can be used to infect splenectomised calves once again after two gerbil passages.

The epizootiological significance of an alternative rodent host for piroplasms affecting cattle merits further investigation. Furthermore, these preliminary findings seem to indicate that the Mongolian gerbil could provide a small animal model for *B. divergens* and other species of cattle piroplasms. This system may prove suitable for immunological investigations and the screening of anti-babesial drugs.

We thank Dr R. E. Purnell for discussion, E. R. Young and G. Osborn for technical help, Professor D. L. Lee for supplying the gerbils and Dr D. G. Baggot for splenectomising them. I. Jebbett prepared the photographs and financial assistance was provided by the Ministry of Overseas Development (Research Project R3270).

T-cell lines which cooperate in generation of specific cytolytic activity

THE unidirectional mixed leukocyte culture (MLC) is characterised by cell proliferation and by the development of cytolytic T lymphocytes (CTL)¹⁻³. In murine MLC, the generation of CTL seems to involve proliferation of at least two subpopulations of responding T cells—T cells of the Ly-2⁺3⁺ phenotype, which differentiate into CTL, and cells of the Ly-1⁺ phenotype, which seem to 'help' or 'amplify' the CTL response^{4,5}. The mechanism by which 'amplifier cells' augment the CTL response is unclear; recent reports have shown, however, that CTL precursors present in populations of long-term MLC or of immune spleen cells^{7,8} can respond to supernatant fluid obtained from allogeneic MLC or mitogen-stimulated spleen cell cultures in the absence of specific antigen. Several groups using such conditioned medium have reported the successful long-term culture of normal and antigen-specific immune T cells in the absence of alloantigen stimuli⁹⁻¹¹. Whereas amplifier supernatant fluids seem to substitute functionally for a T-cell subpopulation (Ly-1⁺?) in the absence of alloantigen, there is only indirect evidence that amplifier cells can be activated by alloantigen to release one or several soluble factors that influence the differentiation or proliferation of

Table 1 Peak levels of ³H-thymidine incorporation

Responding cell	Factor	Stimulating cell		
		Medium	C57BL/6	DBA/2
L2	Medium	197 ± 52	1,104 ± 58	7,501 ± 1,011
	LCA SF	558 ± 384	10,182 ± 5,354	17,228 ± 4,380
	2 ⁰ MLC SF	1,097 ± 444	1,646*	8,705 ± 1,883
L3	Medium	107 ± 48	1,030 ± 368	1,296 ± 176
	LCA SF	702 ± 490	30,865 ± 12,043	53,313 ± 13,744
	2 ⁰ MLC SF	925 ± 585	3,242*	13,035 ± 1,522

The incorporation of ³H-thymidine by L2 or L3 cells cultured with irradiated C57BL/6 (syngeneic) or DBA/2 (allogeneic) spleen cells, or medium alone, was measured in the presence of either LCA or 2⁰ MLC supernatant fluid (SF), or medium alone. Values are mean d.p.m. ± s.e.m. Results from 12 different experiments are included. For details, see Fig. 1.

*Mean d.p.m. calculated from results obtained in two different experiments

CTL¹²⁻¹⁴. We have used modifications of techniques previously described for the long-term culture of immune T cells to isolate several cloned lines of MLC-reactive T cells, including a non-cytolytic T-cell line which, when co-cultured with alloantigen, permits another cell line to proliferate and express specific cytolytic activity.

Primary MLC were prepared by culturing, for 14 d, C57BL/6 (H-2^b) responding spleen cells with irradiated DBA/2 (H-2^d) spleen cells¹⁵. Cells were then collected and restimulated at low density with irradiated DBA/2 spleen cells¹⁶. After 48 h of secondary MLC, cells were collected and cultured at limiting dilution with irradiated DBA/2 spleen cells using medium consisting of equal volumes of 48-h secondary MLC supernatant fluid and Dulbecco's modified Eagle's medium (DMEM)¹⁷ containing 20% fetal calf serum (FCS). Clones of cells appeared in 30% of the wells 8 to 10 d after culturing. Screening of all clones by a micro-⁵¹Cr release assay¹⁸ revealed cytolytic activity by some, but not all, of the cells. Several lines of such cells, some of which are cytolytic, have been maintained in culture for 7 months by weekly transfer with irradiated DBA/2 spleen cells and supernatant fluid obtained from either 48-h secondary MLC (2⁰ MLC) or 48-h cultures of Lewis rat spleen cells stimulated with concanavalin A (LCA). Two of these cell lines have been studied intensively. Both are T cells, as determined by treatment with anti-Thy 1.2 sera: one, designated L2, is non-cytolytic; the other, designated L3, is cytolytic.

The proliferative response of L2, L3, or a mixture of L2 and L3 (L2+L3), indicated by incorporation of ³H-thymidine (³H-TdR), was measured on days 3 and 5 in nine different experiments (Fig. 1a, b). The L2 cells cultured with the original stimulating alloantigen (DBA/2) exhibited peak proliferative responses on day 3, with an average stimulation index of 6.8, when compared with the response of L2 cells cultured with irradiated syngeneic C57BL/6 cells. The proliferative response of L2 cells cultured alone or with irradiated C57BL/6 cells did not change significantly between days 3 and 5, and in terms of viable cells recovered, there was only a 1-to-3-fold increase over L2 cell input compared to a 21- to 44-fold increase in viable cells recovered from cultures of L2 cells and irradiated DBA/2 spleen cells.

In contrast, the proliferative response of L3 cells cultured with irradiated alloantigen was not greater than that observed with L3 cells cultured with syngeneic spleen cells (stimulation index of 1.3 for peak response), and was 5.4 times lower than the response of L2 cells cultured with alloantigen. There was no change in the proliferative response of L3 cells between days 3 and 5; viable cells recovered from cultures of L3 cells with irradiated DBA/2 or C57BL/6 cells increased only 1- to 4-fold over L3 cell input compared to a 0- to 1-fold increase for L3 cells cultured alone.

When L2 and L3 cells were cultured together with irradiated DBA/2 spleen cells, the extent of maximal ³H-TdR incorporation on day 3 appeared to be approximately the sum of the values observed with separate populations of L2 and L3 cells (average stimulation index of 14.2 compared to L2+L3 cells

cultured with irradiated syngeneic C57BL/6 spleen cells). However, the total cell recovery from cultures of L2 + L3 cells with irradiated DBA/2 cells was, on average, twice the sum of the cell recoveries from separate cultures of L2 and L3 cells.

Cytolytic activity was measured with a ^{51}Cr release assay¹⁵ after 3 and 5 days of culture. Although L2 cells proliferated when stimulated with alloantigen in culture (Fig. 1a), these cells never expressed any detectable cytolytic activity (Fig. 1c). Likewise, L3 cells expressed only barely detectable levels of cytolytic activity (mean of <2 lytic units per culture). However, L2 and L3 cells cultured together with irradiated DBA/2 alloantigen developed high levels of cytolytic activity against P-815 target tumour cells (DBA/2 origin) (mean of 71 lytic units per culture). On the other hand, L2 and L3 cells cultured together with irradiated syngeneic spleen cells developed only little lytic activity (mean <4 lytic units per culture). Thus, the inclusion of L2 cells with irradiated DBA/2 alloantigen resulted in an average 22.4-fold increase in cytolytic activity.

Like other investigators⁹⁻¹¹, we have found that 2^0 MLC or LCA supernatant fluid makes possible the proliferation of T cells and the generation of cytolytic activity. The peak proliferative responses for L2 and L3 cells cultured with various supernatant fluids are shown in Table 1. The incorporation of ^3H -TdR by L2 cells cultured with irradiated allogeneic (DBA/2) or syngeneic C57BL/6 spleen cells was significantly higher, on the average, if LCA supernatant fluid was added, as was the total cell recovery. However, the addition of 2^0 MLC supernatant fluid to L2 cells cultured with irradiated DBA/2 cells did not result in any significant increase in either ^3H -TdR incorporation or total cell recovery, except that, in a single experiment, the addition of 2^0 MLC supernatant fluid to L2 cells cultured with irradiated C57BL/6 cells increased total cell recovery 10-fold without any significant increase in ^3H -TdR incorporation. Thus, in the absence of alloantigen, L2 cells cultured with irradiated syngeneic cells could be stimulated to proliferate by the addition of either 2^0 MLC or LCA supernatant fluid. Cytolytic activity, however, was not detectable under any conditions in which L2 cells proliferated.

The effect of 2^0 MLC or LCA supernatant fluid on the peak proliferative response of L3 cells was much greater than the effect on L2 cells (Table 1). The addition of LCA supernatant

fluid to L3 cells cultured with irradiated syngeneic or allogeneic spleen cells increased both the average ^3H -TdR incorporation and cell recoveries 30- to 41-fold, compared to the effect of culture medium only. The effect of 2^0 MLC supernatant fluid was much less than that of LCA supernatant fluid. As seen in Table 1, neither L2 nor L3 cells gave an appreciable proliferative response when they were cultured with 2^0 MLC or LCA supernatant fluid in the absence of additional irradiated cells.

Fig. 2 Cytolytic activity generated by L3 cells cultured with irradiated syngeneic C57BL/6 spleen cells in the presence of LCA supernatant fluid (□), 2^0 MLC supernatant fluid (○), or medium alone (△) after 5 d of culture. Closed symbols, P-815 target cells. Open symbols, AKR-A target cells. a, Cytolytic activity expressed in terms of per cent specific lysis per culture fraction. b, Cytolytic activity expressed in terms of per cent specific lysis at various ratios of effector cells to target cells. For details, see Fig. 1.

These results differ from those reported by Gillis and Smith¹⁰, who found that such supernatant fluids alone were capable of stimulating the proliferation of T cells without addition of cells.

In marked contrast to the results observed with L2 cells, cytolytic activity was detectable whenever L3 cells were stimulated to proliferate. There was a good correlation between the magnitude of the proliferative response and the extent of CTL generation. Figure 2 shows the results obtained in a single representative experiment in which cytolytic activity was

Fig. 1 a, Tritiated-thymidine (^3H -TdR) incorporation by L2 cells (□), L3 cells (▨), and a mixture of L2 and L3 cells (▩) when the cells were cultured alone or with irradiated syngeneic (C57BL/6) or allogeneic (DBA/2) spleen cells in culture medium for 3 d. b, ^3H -TdR incorporation measured after 5 d of culture. c, Cytolytic activity measured against P-815 target cells after 5 d of culture. Results from nine different experiments are presented in which, typically, 1.6×10^4 L2 and/or L3 cells (7 to 8 d after previous transfer) in 0.1 ml were transferred to 3 ml culture wells (Linbro 24-well plate, type 76-033-05) containing 6×10^6 irradiated (1,500 rad) syngeneic (C57BL/6) or allogeneic (DBA/2) spleen cells, or culture medium (DMEM supplemented with 2% heat-inactivated fetal calf serum, 10 mM MOPS buffer, $5 \times 10^{-5}\text{M}$ 2-mercaptoethanol, plus penicillin/streptomycin¹⁷), and either 48-h 2^0 MLC or LCA supernatant fluid (final concentration, 33%), or culture medium, in a final volume of 1.5 ml. Culture plates were then incubated in a humidified atmosphere of 5% CO_2 at 37°C . After 3 and 5 d of culture, individual wells were collected and assayed for both ^3H -TdR incorporation and cytolytic activity. A 0.1-ml culture fraction of each well was placed in triplicate wells of a flat-bottomed microwell tissue culture plate and pulsed with $1 \mu\text{Ci}$ ^3H -TdR ($0.36 \text{ Ci mmol}^{-1}$) for 4 h at 37°C . Cells were then collected on to filter paper strips with an Otto Hiller cell harvester and counted for 2 min in a Searle liquid scintillation counter. Results are expressed as d.p.m. $\pm$ s.e.m. Cytolytic activity was determined with a ^{51}Cr release assay¹⁵. Tumour target cells were labelled with $\text{Na}_2^{51}\text{CrO}_4$ and mixed with serial threefold dilutions of effector cells (replicate wells) in round-bottomed microtitre plates. The plates were incubated for 3.5 h at 37°C and then centrifuged, after which one-half of the supernatant volume in each well was counted in a Packard well-type scintillation counter. The per cent of specific cytotoxicity at various effector-to-target cell ratios was calculated by the formula

$$\% \text{ specific lysis} = \frac{\text{c.p.m. exp.} - \text{c.p.m. spontaneous release}}{\text{c.p.m. max. release} - \text{c.p.m. spontaneous release}} \times 100$$

Maximum release was determined by freeze-thaw lysis of target cells in water; spontaneous release was determined from the amount of isotope released during the assay by target cells incubated with medium only. One lytic unit is defined as the number of effector cells required to lyse 50% of 10,000 target cells within 3.5 h.

compared in terms of culture fraction as well as effector-to-target cell ratio for L3 cells cultured with irradiated C57BL/6 spleen cells in the presence of medium, 2^0 MLC, or LCA supernatant fluid. Measured in lytic units (LU) per culture (Fig. 2a), the addition of LCA supernatant resulted in the expression of the greatest cytolytic activity observed (526 LU per culture) which was approximately 11 times greater than that observed with 2^0 MLC supernatant fluid (46 LU per culture) and 67 times greater than that observed with medium alone. Cytolytic activity was directed specifically towards the original stimulating alloantigen, since there was no detectable lysis when syngeneic or third-party allogeneic tumour cells were used (EL-4, AKR-A, respectively). These differences in CTL activity correlated very well with ^3H -TdR incorporation as well as cell recovery.

When evaluated on the basis of effector-to-target cell ratio, the cytolytic activity generated by L3 cells in response to the addition of 2^0 MLC or LCA supernatant fluid, or of medium alone in the presence of irradiated syngeneic cells, was approximately equal (Fig. 2b). Thus, 50% lysis of 10,000 target cells was observed at effector-to-target cell ratios of 0.36, 0.31 and 0.58, respectively. When L3 cells are cultured with irradiated cells and either medium, 2^0 MLC, or LCA supernatant fluids, they appear to have similar killing potential. Thus, the cytolytic activity of L3 cells is related primarily to the number of cells developing during culture; the 2^0 MLC or LCA supernatant fluids seem to stimulate the proliferation of T cells.

These experiments can be summarised as follows: two cloned lines of T cells, L2 and L3, have been obtained from MLC prepared by co-culturing responding C57BL/6 spleen cells with irradiated DBA/2 alloantigen. L2 cells proliferate in response to alloantigen, but do not express cytolytic activity, whereas L3 cells, which do not proliferate in response to alloantigen unless exposed to 2^0 MLC or LCA supernatant fluid, express cytolytic activity specific for the original stimulating alloantigen. The magnitude of the cytolytic activity seems to be related primarily to the extent of L3 proliferation. The results observed in cultures prepared with L2 and L3 cells together with alloantigen are consistent with the interpretation that alloantigen stimulation of L2 cells results in proliferation and in the release of one or more soluble amplifier factors which bring about the proliferation of L3 cells with a concomitant increase in cytolytic activity. In preliminary experiments, supernatants have been obtained after 2 d from cultures of L2 cells stimulated with alloantigen. L3 cells grown in the presence of 'L2-cell supernatant fluid' together with irradiated allogeneic cells generated cytolytic activity that was 12 times greater than that observed in the absence of 'L2 cell supernatant fluid'. The availability of separate T-cell lines with amplifier or cytolytic activity will simplify the study of interactions involved in the development of cell-mediated immune responses.

Association of a B-cell alloantigen with susceptibility to rheumatic fever

THE possibility that genetic factors determine susceptibility to rheumatic fever following infection with Group A streptococci was suggested by epidemiological and family studies¹. However, with the exception of a slightly increased frequency of Lewis group secretors², the identification of a genetic marker in the patient group has been unsuccessful. In particular, the distribution of HLA-A and B allotypes did not reveal any consistent difference from controls³⁻⁵. We report here that a novel B-cell alloantigen has been found at a significantly increased frequency among patients with rheumatic fever, providing further evidence for the value of B-cell alloantisera as reagents for the demonstration of disease associations with genetic determinants relevant to the immune system. This alloantigen was of particular interest because it was not found to be associated with any recognised HLA-D locus determinant.

The observation that B lymphocytes preferentially express differentiation alloantigens has led to a new approach to the use of genetic markers that might be of special significance to the immune system⁶. These are recognised primarily with alloantibodies that develop as a result of immunisation with paternal antigens during pregnancy. The majority of such alloantisera recognise alloantigens that have extensive biological and chemical homologies with the I-region antigens of the murine histocompatibility system and have been termed 'Ia-like' or simply 'Ia' (ref. 7). Some of these Ia alloantigens are closely related to HLA-D alleles defined in the mixed lymphocyte culture (MLC) reaction, and have been designated HLA-DR. Other B-cell alloantigens are not as readily related and seem to be primarily significant in demonstrating the immunogenetic associations of particular diseases^{8,9}.

Mononuclear cells were isolated from 61 patients with documented rheumatic fever (Jones criteria) attending clinics either in Bogota, Colombia, or New York City, and from age, sex and race matched control individuals. Reagent B-cell alloantisera were selected for their very low T-cell reactivity and further absorbed with pooled platelets. Two assays for B-cell alloantigens were used: mononuclear cells were stimulated with pokeweed mitogen for 4-6 d before staining using an indirect immunofluorescent technique¹⁰, and 'B' cells isolated by depletion of T lymphocytes were used in a modified Amos two-stage microcytotoxicity test⁹.

Twenty-eight lymphoblastoid lines were derived from individuals known to be homozygous for defined HLA-D alleles; 17 were derived from unselected individuals who were defined for all HLA determinants and known to be heterozygous for HLA-D. DR specificities were assigned according to the pattern of reagent serum reactions with the reference cell lines⁹. In the case of sera which detected an alloantigen jointly expressed on cell lines derived from individuals with different HLA-D alleles such as Dw4, Dw7 or Dw10, the specificity of the sera was designated 4 × 7 × 10 (ref. 9). The χ^2 statistic included

Table 1 B-cell alloantigen typing in patients with rheumatic fever

Designation	Reagent serum DR Specificity	New York series (%)		Bogota series (%)		Combined series	
		Normal (52)	Rheumatic fever (21)	Normal (60)	Rheumatic fever (41)	χ^2	Relative risk
883	Undefined	17	71	16	75	50.144	12.94
1,818	1	31	20	24	20	0.906	0.686
1,558	2	28	33	20	30	0.878	1.463
1,033	3	24	25	20	15	0.745	0.68
924	4 × 10	26	25	20	30	0.463	1.26
1,038	4 × 7 × 10	28	35	32	40	1.397	1.54
1,995	5	12	0	10	15	0.125	1.21

the Yates correction for continuity. The relative risk was calculated according to Woolf¹¹ as equal to (patients positive/patients negative) × (controls negative/controls positive). Values greater than one indicate the degree of positive association of a marker with disease.

Reagent serum 883 was identified from among over 200 unselected B-cell alloantisera through its reaction in preliminary studies with a high proportion of patients with rheumatic fever. This and other sera with established DR specificities were used to determine their alloantigen frequencies in two populations of patients with rheumatic fever (Table 1). Serum 883 reacted with 75% of the patients in the Bogota series and 71% of the patients in New York, whereas the frequency of reaction in the two control populations was 16 and 17%, respectively. The association of alloantigen 883 defined by serum 883 with rheumatic fever for the combined series was significant at $P < 0.001$ and the relative risk was 12.9. We have not shown the unremarkable frequency of reaction with serum 883 among patients with a variety of other diseases, including tuberculosis, leprosy, post-streptococcal glomerulonephritis, multiple sclerosis, rheumatoid arthritis and systemic lupus erythematosus.

The expression of a number of Ia-like alloantigens, including some which were related to HLA-D specificities, was studied with 19 B-cell alloantisera. The frequency of alloantigens detected by these reagents among patients was not significantly different from their respective control groups. The results for six sera with representative specificities are included in Table 1.

Attempts were made to define the specificity of alloantiserum 883 using 28 B-cell lines derived from individuals homozygous for the various MLC D-locus alleles (Dw1, Dw2, Dw3, Dw4, Dw5, Dw6, Dw7, Dw10 and Dw11) and selected for their suitability as typing cells. Serum 883 did not react with any of these defined homozygous cell lines. In contrast, both peripheral blood B cells and B-cell lines derived from 17 individuals known to be heterozygous at the D locus gave strong reactions with serum 883 in three instances. However, the reactivity could not be correlated with a defined MLC specificity. Similarly, using B lymphocytes from 52 normal subjects, no significant association of the presence of alloantigen 883 could be established with any HLA-A, B or D alleles.

The recognition of alloantigen 883 through the disease association with rheumatic fever emphasises the usefulness of directly screening disease populations with multiple antisera as a means of gaining insight into genetic factors that otherwise might not be as readily apparent. The interpretation that alloantigen 883 is an allele of a segregant series that is either a second Ia locus unrelated to HLA-D or a totally distinct B-cell locus is favoured by three observations: the absence of any relation of alloantigen 883 to a defined HLA-D allele; the lack of a reciprocal decrease of any DR alloantigens among the patient group that would have been expected if the DR alloantigens were alleles of alloantigen 883; the occurrence in certain individuals of alloantigen 883 as a third specificity in addition to two conventional and non-cross-reacting DR alloantigens and their associated HLA-D determinants.

The association of this B-cell alloantigen with rheumatic fever provides direct support for the concept that an immunogenetic factor is relevant to the development of rheumatic fever after streptococcal infection.

NK cell-sensitive T-cell subpopulation in thymus: inverse correlation to host NK activity

NATURAL KILLER (NK) cells have been shown to have an important role in resistance to some tumours (see ref. 1 for review) and it has been suggested that these NK cells may represent a T cell and macrophage-independent surveillance mechanism² similar in principle to the theory proposed by Burnet³ and Thomas⁴. Recent observations have led to the speculation that NK cells may also have a physiological role *in vivo* as NK cells were closely associated with the rejection of bone marrow grafts^{5,6}. Although the target 'antigens' of NK cells have not yet been fully defined⁷, a wide range of malignant and non-transformed cells, including normal thymocytes¹⁷ and bone marrow cells⁸ are also sensitive to low levels of NK-mediated cytotoxicity. We provide evidence here to support the view that the NK cells may be involved in the control of normal T-cell subpopulations within the thymus.

Thymocytes from 2-week-old A/Sn mice were lysed in a 3 h ⁵¹Cr release assay with nylon wool passed CBA spleen cells

as NK effectors (Fig. 1). As shown below in Fig. 4, this lytic effect was dose-dependent at effector to target cell ratios below 25:1, whereas higher numbers of effector cells resulted in a marked decrease in lysis for unknown reasons. The active killer cell shared the cell surface characteristics of mouse NK cells (data not shown), and showed the same strain distribution as previously reported for mouse NK cells¹ (Fig. 3). Moreover, cold targets inhibition assays have shown that NK cells recognise the same target structure on A/Sn thymocytes as on the NK-sensitive tumour targets YAC-1 (data not shown). Low but significant levels of sensitivity to NK-mediated lysis were also exhibited by bone marrow, peripheral blood and spleen cells from 1-2-week-old A/Sn mice (Fig. 1). Conversely the organ distribution of NK reactivity in adult mice invariably showed that the thymus is the organ of least NK cytolytic potential (shown for strain CBA in Fig. 1) as previously reported⁹.

Fig. 1 Organ distribution of NK-sensitive cells in various lymphoid organs of 2-week-old A/Sn mice. Lymphocytes were enriched from peripheral blood by Ficoll-isopaque gradients followed by iron-magnet treatment to remove monocytes-macrophages. Spleen cells were treated with hypotonic shock followed by passage through nylon-wool adherence column to enrich for T lymphocytes. Cells from each organ were used as targets (solid bars) in a conventional 3 h ⁵¹Cr release assay using nylon wool-passed CBA spleen cells as NK effector cells at an effector to target cell ratio of 10:1 as described previously⁵. Open bars indicate organ distribution of NK reactivity in a standard NK assay using the YAC-1 tumour as target.

The NK sensitivity of thymocytes varied markedly with the age of the thymus donor. The highest sensitivity was observed with thymocytes from very young donors (<1-2 weeks) whereafter a gradual decrease of NK sensitivity occurred (Fig. 2). The mice that were used as thymocyte donors were also tested for their spleen NK activity. As shown in Fig. 2, the onset of NK activity around the third week after birth occurred simultaneously with a fall in the NK sensitivity of the thymocytes from the same mice. In old mice, NK activity as well as thymocyte sensitivity was low or absent.

The genetic control of thymocyte sensitivity was also investigated in several other strains of mice previously classified as high or low NK responders in extensive genetic studies (see ref. 1 for review). Again the inverse correlation between thymocyte sensitivity and NK activity was striking (Fig. 3). Thus, thymocytes from mice of low NK reactive strains (A, A.CA and AKR) displayed higher sensitivity to lysis than thymocytes from NK high reactive (CBA or DBA/2 × C57BL/6 F₁ hybrids) or mid reactive strains (C57BL/6 and DBA/2). Ten separate experiments yielded a mean lysis of 13.4% for A/Sn and 4.8% for CBA thymocytes ($P < 0.001$) from age-matched mice. The same relative differences in thymocyte sensitivity appeared when NK effector cells were taken from CBA, C57Bl or A strains (Fig. 3). As high NK levels were invariably associated

Fig. 2 Inverse correlation between the age dependence of splenic NK activity and the sensitivity of thymocytes to NK-mediated lysis. Thymocytes from three mice of each age were pooled and used as target cells in a 3 h cytolytic assay with nylon wool-passed CBA spleen cells as effector cells at an effector to target cell ratio of 50:1 (○). Spleen cells from the same mice were used as effector cells in a 3 h NK assay at an effector to target cell ratio of 50:1 with the YAC-1 tumour as target (×). *a*, Experiment with the CBA strain, *b*, with the A/Sn strain as thymocyte target and spleen cell effector donor.

with low levels of sensitive thymocyte targets it was important to determine the effect of NK boosting agents on thymocyte sensitivity in the same animal.

It is known that NK activity can be markedly augmented by interferon as well as several interferon inducing agents^{10,11}; all known to exert anti-tumour effects *in vivo*^{12,13}. When two such agents, tilorone (Fig. 4) and polyI:C (unpublished observation) were administered to young strain A mice a substantial increase in NK activity was apparent. However, thymocytes from these same animals were much less sensitive to NK-mediated lysis than thymocytes from controls, which again demonstrates the inverse relationship between levels of NK reactivity and thymocyte sensitivity to lysis.

There are various possibilities to consider when trying to explain this inverse relationship. The NK target distribution may be a direct consequence of the NK activity. Thus, in organs with high NK activity (spleen, peripheral blood, lymph node) or in individual mice of high reactive age or genotype, the natural target could simply be eliminated by the cytolytic effect of the NK cells, a process which would be enhanced by activation of the NK cells with tilorone. It is equally possible, however, that the NK-sensitive thymocytes and NK cells lie on different branches of a single differentiation pathway and thereby compete for a common progenitor. A third alternative is that

Fig. 3 Strain distribution of thymocyte sensitivity for NK lysis and its inverse correlation with genetically controlled NK reactivity. *a*, NK-low reactive strains; *b*, NK-high reactive strains; *c*, NK-intermediately reactive strains. Thymocytes were pooled from three mice at 3 weeks of age and used as target cells in a 3 h NK assay. Bar values represent the mean % lysis of triplicate samples $\pm$ s.e.m. Nylon wool-passed spleen cells from A/Sn (■), C57BL/6 (□), and CBA (▨) mice were used as a source of NK cells at an effector to target cell ratio of 10:1. These mouse strains were previously classified as to their genetically controlled NK reactivity¹.

Fig. 4 Increased NK reactivity (b) and decreased NK sensitivity of thymocyte targets (a) following administration of the interferon inducer tilorone. Two-week-old A/Sn mice were each given 0.8 mg tilorone orally and 14 h later thymocytes from treated (○) or sham treated (×) littermates were tested as target cells in a 3 h cytolytic assay with nylon wool-passed CBA spleen cells as effectors (a). The total number of thymocytes recovered from tilorone-treated or control mice was 65 and 60×10^6 , respectively, indicating that the NK-sensitive population had not been eliminated by a cortisone-mediated effect¹⁶, which would have caused a marked cellular depletion of the thymus. b, increased NK reactivity in spleen cells from the same tilorone-treated (○) and control (×) mice as tested in a standard 3 h NK assay against the YAC-1 tumour target. The % lysis values are low as these mice are below optimum NK age (Fig. 2).

NK activity and the frequency of natural targets may both be regulated by a common extrinsic agent such as interferon. Trinchieri *et al.*¹⁴ have demonstrated that interferon can have opposing effects of increasing NK activity and decreasing target sensitivity for NK lysis. However, as the role of interferon in the age and genotype regulation of NK cells is not yet established, the two former explanations may be more likely. Preliminary results indicate that the NK-sensitive targets belong to the immature, cortisone-sensitive subpopulation of thymocytes. As NK cells are present in the bone marrow but not in the thymus, we will test the hypothesis that these 'precursor' T cells are destroyed in the marrow before, or during, their migration to the thymus.

In summary we have found an NK-sensitive subpopulation of T cells in the thymus. The frequency of these natural targets was inversely correlated to the level of NK reactivity in the thymocyte donor as judged by four separate criteria of organ distribution, age dependence, genotype variation and the effect of interferon inducers. Note that T-cell lymphomas in particular seem to be the most sensitive tumours for NK-mediated effects^{2,15}. It is an exciting possibility that the autologous NK target may in fact correspond to the target cell for leukaemic transformation and NK cells therefore may have a central role as a homeostatic control mechanism for this potentially neoplastic population.

Activation of complement by cytoskeletal intermediate filaments

INTEREST in cytoplasmic intermediate (10 nm) filaments has grown since the successful immunohistochemical differentiation of these filaments from microtubules and microfilaments^{1,2}. Despite the widespread occurrence of intermediate filaments in various cell types, little is known about their function^{1,3,4}. A cytoskeletal nucleus-anchoring role has been suggested based on their intracellular distribution, their connections to the plasma membrane and nucleus, and their marked insolubility in detergents and salt solutions^{5,6}. The presence of autoantibodies against intermediate filaments in the sera of patients^{7,8} suggests that these filaments can be involved in pathogenetic processes. We report here that in studies on possible pathogenetic mechanisms involving intermediate filaments, antibody-independent binding of complement components to intermediate filaments has been observed. Initial observations were made using cultured human embryonal fibroblasts, as cytoplasmic filaments present in these cells have been characterised by using both immunological markers and drugs capable of selectively altering the morphology of microfilaments, intermediate filaments and microtubules^{1,7}. Subsequent studies showed complement binding to similar cytoplasmic structures of other cultured cells and also cells in tissue sections.

Cultured cells were made permeable to serum macromolecules by treatment with the non-ionic detergent NP40 (ref. 9) before incubation with serum. Complement components bound to cellular constituents were detected by incubation with fluorochrome-conjugated antibodies against human C1q, C4 and C3. Antibody conjugates detecting fibrin and immunoglobulins G, M and A served as controls. Direct immunofluorescent staining of fibroblasts incubated with fresh normal human serum revealed strong binding of the C1q subcomponent of C1 and of C4 and C3. A fine fibrillar cytoplasmic distribution of all three complement components was seen (Fig. 1a) using cultured fibroblasts originating from three different human fetuses. No binding of immunoglobulins or fibrin could be demonstrated. There was no staining if the detergent treatment was omitted, nor did staining occur with anti-complement conjugates alone. The complement binding phenomenon thus seemed to be independent of serum antibodies and could be demonstrated using 50 normal human sera without detectable antibodies against fibroblasts. Furthermore, purified C1q¹⁰ bound to cultured fibroblasts in a way similar to C1q of serum. C4 and C3 binding was inhibited in the presence of 10 mM EDTA and EGTA, which inhibit complement activation by chelating Ca^{2+} and Mg^{2+} (ref. 11). Binding of C1q occurred despite inhibition of C4 and C3 binding. The results indicate that C1q binding initiates Ca^{2+} - and Mg^{2+} -dependent complement activation by the classical pathway.

Fig. 1 Direct immunofluorescent staining of cultured cells (a–e) and human fetal connective tissue (f) demonstrating specific binding of complement components to cytoskeletal intermediate filaments. A fine fibrillar cytoplasmic network corresponding to the distribution of intermediate filaments is visualised in cultured human fetal fibroblasts. *a*, The cells were cultivated on coverslips in RPMI 1640 (Grand Island Biological) supplemented with 10% heated fetal calf serum (56 °C, 60 min), fixed in 3.5% phosphate-buffered paraformaldehyde to conserve cellular morphology, and treated with a 0.05% solution of the non-ionic detergent Nonidet P40 (NP40, BDH) to make cells permeable to serum macromolecules⁹. The cells were incubated with normal human serum (diluted 1:10 in saline) for 30 min at room temperature, washed in saline and treated with fluorescein isothiocyanate-conjugated rabbit anti-Clq conjugate (Behringwerke). *b*, Fibroblasts treated with vinblastine sulphate (Lilly, 10 $\mu\text{g ml}^{-1}$) for 4 h were similarly treated with serum and stained for bound Clq. Note typical perinuclear bundles of intermediate filaments decorated by bound Clq. *c*, Fibroblasts treated with 0.1% detergent Triton X-100 (BDH) in saline for 15 min and then extracted with low and high ionic strength extraction buffers LAMES and HAMES⁶ containing 1 mM enzyme inhibitor phenylmethylsulphonylfluoride (Sigma) still exhibited an insoluble network of intermediate filaments attached to the substratum. This network retained the ability to bind complement. Binding of complement component C3 demonstrated after staining with TRITC-anti-human C3c (Behringwerke). *d*, Fibroblasts depleted of culture medium become permeable to serum constituents and exhibit irregular binding of Clq to intermediate filaments without pretreatment with detergent. Treatment otherwise as described in *a*. *e*, After incubation with serum, lymphoma cells K562 exhibit binding of complement component Clq to perinuclear fibrillar structures very similar to intermediate filaments in fibroblasts treated with microtubule disrupting drugs (*b*). *f*, Binding of complement components to cytoplasmic fibrils of fetal human mesenchymal cells was similar to the binding observed with cultured fibroblasts. Cryostat section of dermal connective tissue was treated as described in *a*. Magnifications $\times 500$.

The cytoplasmic structures binding Clq were readily identified. The localisation of bound Clq was indistinguishable from that produced by antibodies against intermediate filaments but was clearly distinct from that seen with antibodies against actin containing microfilaments or against microtubules^{3,7}. A typical change in the complement binding pattern, consistent with reorganisation of intermediate filaments³, was achieved by treating fibroblast cultures with the microtubule disrupting drugs, demecolchicine and vinblastine⁷ (Fig. 1*b*). Disruption of microfilaments³ with cytochalasin B did not alter the pattern of complement binding.

Intermediate filaments bound complement even after the cells had been subjected to treatment with non-ionic detergent Triton X-100 and subsequent extraction with high and low ionic salt solutions^{5,6} (Fig. 1*c*). Earlier studies have shown that these treatments leave only intermediate filaments in the cell residues, microfilaments and microtubules having been disrupted⁵. This further confirmed that Clq is bound to intermediate filaments and not to other cytoskeletal structures. Intermediate filaments able to bind complement were also demonstrated in nonviable fibroblasts permeable to serum proteins without detergent treatment, in cultures depleted of nutrient medium for 24 h (Fig. 1*d*). Preliminary studies have shown that cultured cells such as glia and glioma MG-251 cells bind complement in a similar way to fibroblasts, whereas perinuclear coiling bundles were observed in lymphoma cells K562 (ref. 12) (Fig. 1*e*). Further studies indicated that complement binding is not a property unique to cultured cells; this was shown most clearly in cryostat sections of fetal connective tissue (Fig. 1*f*).

The results suggest that Clq binding and complement activation through the classical pathway by intermediate filaments of different cell types is an antibody-independent recognition mechanism. Antibody-independent activation of Clq seems to be physiologically important and has been shown to operate against bacterial lipopolysaccharides¹³, virus-infected cells¹⁴, parasites¹⁵ and autologous cellular constituents such as heart subcellular membranes¹⁶, erythrocyte membranes¹⁷ and DNA¹⁸. Clq binding to intermediate filaments followed by classical complement pathway activation and accumulation of inflammatory cells¹¹ may be an elimination mechanism for poorly soluble cytoskeletal residues of damaged cells. It is tempting to speculate that failure of this mechanism results in chronic inflammatory reactions or extra-cellular deposition of intermediate filament residues in the form of morphologically and immunologically identical hyaline¹⁹ or amyloid^{20,21}.

We thank Ms P. Kaipainen and Ms J. Gluschkoff for technical assistance. Dr L. Andersson provided the K562 cells and Dr E. Saksela the glioma cells. The study was supported by grants from the Sigrid Jusélius Foundation and the Finnish MRC.

Diminished microtubules in fibroblast cells derived from inherited dystrophic muscle explants

MUSCULAR DYSTROPHY of the Duchenne type is inherited in a recessive, sex-linked fashion. The aetiology of the disease is still unclear but biochemical and morphological studies strongly suggest a cell surface membrane abnormality in Duchenne muscular dystrophy¹⁻⁷. Even though there are artefacts due to surface condensation of water, freeze-fracture studies of skeletal muscle from patients with Duchenne dystrophy show a depletion of intramembrane particles in the protoplasmic and environmental faces of the muscle plasma membrane^{8,9}. In contrast, Ketelsen's freeze-fracture studies indicated that the number of particles in the inner membrane fracture face in muscular dystrophy increased two- or threefold beyond normal¹⁰. In other studies, it was demonstrated that patients and carriers of Duchenne muscular dystrophy exhibited diminished cap formation in their lymphocytes^{11,12}. Although these experiments clearly support a membrane defect in muscular dystrophy, whether this is related to the aetiology of the disease is not yet clear. Several of these studies indicate that this membrane defect is an early and perhaps primary one in the aetiology of Duchenne's muscular dystrophy⁷. Even though the primary lesion in muscular dystrophy is usually thought to be

myogenic or neurogenic the reported abnormalities in the lymphocyte^{11,12} and erythrocyte membrane¹³ indicate that the expression of muscular dystrophy may not necessarily be restricted to these tissues. There have been many studies on the dynamic interrelationships between cytoplasmic structures and the cell surface^{14,15} and models have been proposed which suggest that changes in the state of the cytoplasmic microfilaments and microtubules can alter the mobility and distribution of membrane surface receptors¹⁶. In an attempt to determine if the membrane defect in muscular dystrophy might be correlated with a cytoskeletal alteration, we have studied the distribution of cytoplasmic microfilaments (actin) and microtubules (tubulin) in fibroblasts derived from muscle explants of both normal and dystrophic inbred chickens using indirect immunofluorescence methods with monospecific antibodies directed against actin and tubulin. We report here that fibroblasts from explants of cardiac and skeletal muscle of dystrophic chickens show a dramatic reduction in the appearance of intact interphase microtubules compared with those from normal chickens.

Fig. 2 Cells derived from normal cardiac explants (a) of a 7-d-old chicken possess full cytoplasmic microtubule complexes, whereas similar cells obtained from dystrophic cardiac muscle (b) possess diminished cytoplasmic microtubule complexes. Tubulin antibody stain. Scale bar, 10 μ m.

Fig. 1 Cells derived from cardiac explants obtained from 7-d-old normal (a) and dystrophic (b) chickens exhibit no apparent difference in morphology or distribution of cytoplasmic actin stress fibres. Actin antibody stain. Scale bar, 10 μ m.

In our initial studies, we chose muscle explants from fertilised eggs and newborn chickens. The birds of line 413 are characterised by the onset of inability to right themselves about 3 weeks after hatching. The dystrophic chicken lines are considered to be a good model for human dystrophy because the progressive developmental onset of the disease resembles that seen in Duchenne's dystrophy. Line 413 birds are similar to the line 304 birds from which they were derived with regard to muscle fibre diameter, cytochemistry, acetylcholinesterase (AChE) levels, electromyography and serum enzymes¹⁷.

Small pieces (<1 mm³) of cardiac and skeletal muscle were placed on glass coverslips in 35-mm Petri dishes and allowed to attach firmly for 10 min before addition of 2 ml CMRL-1066 culture medium (Gibco) containing 10% horse serum and 5% fetal bovine serum. After 7 days incubation, a monolayer of cells grew out from these muscle explants which seemed morphologically to be primarily fibroblasts. In similar studies it has been reported that the cells which grow out from these muscle explants may in fact be aberrant precursors of myoblasts or an abnormal form of fibroblastic connective tissue¹⁸. The coverslips with attached fibroblast cells were rinsed in phosphate-buffered saline (PBS), fixed in 3% formaldehyde-PBS for 20 min, and then extracted in acetone at -10 °C for 7 min. The cells were rehydrated from acetone in PBS and incubated with the antibody (0.1 mg ml⁻¹ for anti-actin; 0.05 mg ml⁻¹ for anti-tubulin) for 45-60 min at 37 °C. Following four 15-min rinses in PBS, the cells were incubated in fluorescein-conjugated goat anti-rabbit IgA (Mely) diluted 1:6 with PBS. Finally, they were rinsed

Table 1 Presence of cytoplasmic microtubule complex in different muscle types

Muscle tissue type	No. of animals used	Age of animal	No. of cultures counted	No. of cells +CMTC	No. of cells -CMTC	Total no. of cells	% +CMTC
Normal cardiac	6	12-d embryo	8	577	203	800	72%
Dystrophic cardiac	5	12-d embryo	7	471	231	702	67%
Normal skeletal	6	12-d embryo	8	545	245	800	68%
Dystrophic skeletal	5	12-d embryo	7	507	193	700	72%
Normal cardiac	6	1-d chick	8	636	164	800	80%

+CMTC, full cytoplasmic microtubule complex; -CMTC, diminished cytoplasmic microtubule complex. Normal control cardiac and skeletal fibroblast cells possess 60–80% +CMTC regardless of the age of the animal. The remaining control cells with a -CMTC are accounted for by those that are in mitosis, or other phases of the cell cycle in which the +CMTC is not apparent. Also, the cell population is not homogeneous and other cell types not containing full CMTC may be present. Fibroblast cells derived from dystrophic cardiac and skeletal muscle explants exhibit a loss in organisation of the cytoplasmic microtubules after hatching of the chick. This reduction of organisation and complexity of the CMTC becomes strikingly evident in the 14-d-old dystrophic chick.

four times for a total of 60 min and mounted on glass slides in a drop of glycerol: PBS (9:1 by volume at pH 9.5–10.0)¹⁹.

Figure 1 shows fibroblasts derived from normal and dystrophic cardiac explants obtained from 7-d-old chickens. These cells were stained with anti-actin to show the distribution of actin microfilaments and, as can be seen in Fig. 1, no differences are apparent. Figure 2 also shows fibroblasts derived from normal and dystrophic cardiac explants obtained from 7-d-old chickens which were studied for their microtubule distribution. The normal cells (Fig. 2a) contain a full complex of microtubules while the dystrophic cells (Fig. 2b) contain a diminished complex of microtubules. Figure 3 illustrates fibroblasts derived from normal and dystrophic skeletal muscle treated identically to those in Fig. 2. These observations indicate that there is a dramatic alteration in the distribution of intact interphase microtubules in cells derived from dystrophic tissue.

These differences in the distribution of microtubules cannot be accounted for on the basis of membrane impermeability to the tubulin antibody in the dystrophic cells for the following reasons: first, in the experiments with antibodies against actin, both the normal and dystrophic cells stained identically; second, the microtubules in the dystrophic cells are only diminished during interphase. The dystrophic cells grow at approximately the same rate as the normal cells and mitotic spindles composed primarily of microtubules seem to be identical by immuno-

fluorescence. Also, recent observations have indicated that rounded and flattened cell morphologies are variable in the expression of microtubules²⁰, but in this case, both the normal and dystrophic cells maintain a flattened morphology and thus, the diminished complex of microtubules in dystrophic fibroblasts does not seem to be related to overall cell shape. These results are consistent with a defect in the control of expression of interphase microtubule organising centres.

Other possible interpretations of these findings can be extrapolated from the recent work of others^{18,19}. Dise *et al.*²¹ reported results which indicated that an alteration occurs in the regulation of erythrocyte membrane function by calcium in human muscular dystrophy and Irish *et al.*²² have reported an alteration in the calcium binding component of the troponin complex (troponin-C) in avian muscular dystrophy. As microtubules are sensitive to intracellular calcium levels²³, our results could be interpreted to support a calcium alteration in muscular dystrophy.

In an attempt to analyse these findings further, a study of various stages of development was undertaken. As can be seen in Table 1, the diminished complex of microtubules is not present in fibroblasts derived from explanted cardiac and skeletal muscle obtained from embryonic material. Explants from 1-d-old dystrophic chickens show the first indication of loss of microtubules and this reduction is maximised approximately 2 weeks after hatching. These studies indicate that diminished microtubules in fibroblasts derived from inherited dystrophic muscle explants may be a progressive developmental defect and studies are now in progress to analyse the microtubules in lymphocytes and platelets from carriers and individuals with Duchenne's muscular dystrophy.

This research was supported in part by grants to J.W.S. from the Muscular Dystrophy Association and NIH HL20643 and HL00422. We thank Drs H. Feit, R. G. W. Anderson and W. Snell for valuable discussions and G. M. Fuller for the tubulin antibody.

Possible role of retinoic acid binding protein in retinoid stimulation of embryonal carcinoma cell differentiation

RETINOIDS, naturally occurring and synthetic analogues of vitamin A, are involved in the maintenance and differentiation of epithelial tissue^{1–3}. Furthermore, it has been reported that these compounds inhibit the growth of certain nontransformed and virally and chemically transformed cell lines^{4,5}. Recently, it has been shown that retinoic acid stimulates the differentiation of embryonal carcinoma cells^{6,7}, undifferentiated early embryonic-like cells present in teratocarcinomas. Embryonal carcinoma cell lines differ widely in their capacity to differentiate: a distinction has been made between 'pluripotent' and 'nullipotent' cell lines^{8,9}. In contrast to the latter, pluripotent embryonal carcinoma cells differentiate when injected into mice⁸ or when cell aggregates are formed *in vitro*¹⁰; some cell lines differentiate quite readily even when grown in monolayer culture. We have shown⁷ that retinoic acid not only stimulates the differentiation of pluripotent embryonal carcinoma cell lines, but also induces differentiation of the so-called nullipotent embryonal carcinoma cell lines nulli SCC1 and 6050 AJ. We show here that this effect is not limited to retinoic acid but that several other retinoids have the ability to stimulate differentiation of at least one embryonal carcinoma cell line, PCC4.aza1R. Furthermore, we present evidence to suggest that the action of retinoids may be mediated by a retinoic acid binding protein.

PCC4.aza1R embryonal carcinoma cells do not differentiate when maintained in the exponential phase or when grown to confluency; however, when cell aggregates are formed in a bacteriological dish and transferred to a tissue culture dish, outgrowth of differentiated cells is observed after a 2-d incubation period^{7,10}. The differentiated cells can be distinguished from PCC4.aza1R cells by their morphology and the production of plasminogen activator: outgrowths of PCC4.aza1R aggregates containing differentiated cells secrete plasminogen activator as indicated by the fibrin-agar overlay technique¹¹, whereas those containing no differentiated cells do not. The proportion of PCC4.aza1R aggregates giving rise to differentiated cells depends on the duration of incubation of the cell aggregates in bacteriological dishes. In standard conditions, at least 7 d of incubation are required before any PCC4.aza1R aggregates will produce differentiated cells; however, in the presence of 10^{-5} M retinoic acid, 100% of 1-day-old aggregates give rise to

Fig. 1 Sucrose gradient analyses of the binding of ^3H -retinoic acid to cytosol and nuclear supernatants of PCC4.aza1R cell homogenates. Cells grown in monolayer culture in Dulbecco's modified Eagle's medium were collected and washed three times in phosphate-buffered saline (PBS). After resuspension in 10 mM Tris-HCl buffer (pH 7.4) containing 2 mM MgCl_2 and 7 mM β -mercaptoethanol, cells were homogenised with a Dounce homogeniser. Lysed cells were centrifuged for 5 min at 1,000 g. The supernatant was collected and centrifuged at 110,000g for 1 h. The resulting supernatant is referred to as the cytosol fraction. The nuclear pellet was resuspended in 0.32 M sucrose plus 3 mM MgCl_2 and layered at the top of 1.7 M sucrose and centrifuged at 22,000 r.p.m. for 1 h in a SW27 rotor. The resulting pellet contains purified nuclei. The nuclei were homogenised by sonication and centrifuged at 110,000g for 1 h. The resulting supernatant is referred to as the nuclear supernatant. *a*, The cytosol supernatant was incubated with 5×10^{-8} M ^3H -retinoic acid ($30.9 \text{ Ci mmol}^{-1}$) alone (●), ^3H -retinoic acid plus 5×10^{-6} M unlabelled retinoic acid (○) or unlabelled retinol (▲). Incubation mixtures were subjected to sucrose gradient centrifugation on linear 5–20% (w/v) sucrose gradients in PBS for 18 h at 220,000g. Fractions were collected and analysed for tritium content with a liquid scintillation spectrometer. *b*, Sucrose gradient analyses of nuclear supernatant of PCC4.aza1R cells incubated with ^3H -retinoic acid (○) and nuclear supernatant prepared after intact cells were incubated with 10^{-6} M ^3H -retinoic acid for 2 hr at 37°C (●). Bovine serum albumin (68,000), ovalbumin (43,000) and myoglobin (17,000) sedimented in separate gradients at fraction numbers 3, 5, and 20, respectively.

differentiated cells^{7,10}. Using the aggregation procedure, we tested several analogues for their ability to stimulate differentiation of PCC4.aza1R cells (Table 1). In the control, (in the absence of retinoids), none of the PCC4.aza1R aggregates produce differentiated cells whereas in the presence of retinoic acid (no. 4) 100% of the aggregates differentiate. In general, the acid analogues are the most potent stimulators, although some (nos 12 and 16) are inactive.

A retinoic acid binding protein has recently been detected in the cytosol and nuclei of several tissues^{12–15}, and we have tested for the presence of such a protein in embryonal carcinoma cells. The 110,000g supernatant fraction of PCC4.aza1R cells readily binds ^3H -retinoic acid, demonstrating on sucrose gradient analysis a single, symmetrical receptor peak with a sedimentation coefficient of approximately 2S (Fig. 1a). A similar binding protein is observed in the cytosol of embryonal carcinoma cell lines OC 15 and nulli SCC1 (unpublished observations). Unlabelled retinoic acid competes with ^3H -retinoic acid for the binding site but retinol does not (Fig. 1a). Retinoic acid has a high affinity for the binding protein; an apparent dissociation constant of 2.3×10^{-8} can be calculated from the data in Fig. 2. No retinoic acid was detectable when isolated nuclei were homogenised and the supernatant fraction incubated with ^3H -retinoic acid. However, binding of retinoic acid was observed in nuclear fractions prepared from cells preincubated with ^3H -retinoic acid (Fig. 1b). This situation is very similar to that of steroid hormone receptors¹⁶, where nuclear binding is only detectable after hormone-receptor interaction in the cytoplasm.

Table 1 Comparison of the capacity of retinoids to stimulate the differentiation of embryonal carcinoma cells with their ability to compete for the binding site of the retinoic acid binding protein

Basic chemical structure	R	No.	% of aggregates differentiating			Competition for binding site
			10^{-5} M	10^{-6} M	10^{-7} M	
	CH ₂ OH	1	T	0	0	—
	CH ₂ OCH ₃	2	0	0	0	—
	CHO	3	50	0	0	—
	COOH	4	100	100	100	+
	COOCH ₃	5	0	0	0	—
	CH ₂ OCOCH ₃	6	100	10	0	—
	CH ₂ OH	7	0	0	0	—
	CH ₂ OCH ₃	8	0	0	0	—
	COOH	9	100	100	100	+
	COOC ₂ H ₅	10	0	0	0	—
	COOH	11	100	100	100	+
	COOH	12	0	0	0	—
	COOH	13	100	80	0	+
	COOC ₂ H ₅	14	0	0	0	—
	COOH	15	100	100	100	+
	COOH	16	0	0	0	—

Embryonal carcinoma cells (10^5 cells per dish) were added to Dulbecco's modified Eagle's medium supplemented with 10% fetal calf serum, 100 U ml^{-1} each of penicillin and kanamycin and $100 \mu\text{g ml}^{-1}$ streptomycin in a bacteriological dish (6 cm diameter). In these conditions cells do not adhere to the dish but proliferate and form aggregates. After 48 h incubation, aggregates were transferred to a tissue culture dish containing complete medium supplemented with the indicated retinoid dissolved in ethanol or with ethanol alone in the control (0.15% v/v final concentration). The aggregates attach to the dish and grow out. After 2 d of incubation the percentage of aggregates containing differentiated outgrowths was determined either on the basis of morphology or plasminogen activator production by the fibrin-agar overlay method¹¹. These criteria correlated very well with each other. Differentiation in control conditions (in the absence of retinoids) was zero. Analysis of competition for the binding site was carried out by incubating the $110,000g$ supernatant fraction, obtained as described in the legend to Fig. 1, with $5 \times 10^{-8} \text{ M } ^3\text{H-retinoic acid}$ ($30.9 \text{ Ci mmol}^{-1}$) plus 100-fold excess of the indicated retinoid for 1 h at 4°C . Competition was determined by sucrose gradient analysis as described in the legend to Fig. 1. Analogues 1 and 9 are retinol and retinoic acid, respectively; + and — indicate, respectively, the analogue's ability and inability to compete for the binding site. T, toxicity.

To investigate the possibility that the observed binding protein might be involved in the action of retinoids on embryonal carcinoma cells, the ability of the various retinoids to stimulate

Fig. 2 Plot of $^3\text{H-retinoic acid}$ binding by PCC4.aza1R cytosol as a function of retinoic concentration. Binding assays were carried out as described in Fig. 1. The dissociation constant was determined according to the procedure described by Wiggert *et al.*¹⁴ and represents an average of the dissociation constants of all binding sites in the 2S fraction.

differentiation of PCC4.aza1R cells was compared with their capacity to compete with $^3\text{H-retinoic acid}$ for binding sites on the retinoic acid binding protein. Table 1 shows that these two activities correlate well with each other. Retinyl acetate seems to be an exception because it does not compete for the binding site but is moderately active; however, this might be due to metabolism of the retinyl acetate into an active analogue. Modification of the cyclohexene ring of retinoic acid often does not interfere with the ability of the analogue to stimulate differentiation or to compete for the binding site, whereas substitution of the carboxylic acid group affects these activities severely. This suggests that the carboxylic acid group plays an important part in the interaction of these compounds with the binding protein.

The results presented here show that the induction of differentiation of embryonal carcinoma cells is not limited to retinoic acid but that several other analogues are also active. This activity correlates well with the ability of these compounds to compete for the binding site of the retinoic acid binding protein and suggests that their action on differentiation may be mediated by this binding protein. The results on the binding of retinoic acid to nuclear fractions indicate a similarity with the binding of steroid hormones to their receptors¹⁶ and suggest that retinoids may act as a mechanism similar to that of steroid hormones, that is, that complexes of retinoic acid and binding protein are transported into the nucleus, whence they modify gene transcription. However, on the basis of their observations that retinoids are involved in glycosylation reactions, De Luca *et al.*¹⁷ have proposed that retinoids may act through an altered biosynthesis of specific glycosylated intermediates. This hypothesis cannot as yet be ruled out.

Several of the retinoids which are potent stimulators of differentiation of embryonal carcinoma cells are also very effective in reducing the occurrence and retarding the growth of certain tumours^{3,18-20}. The test described above might be useful as an *in vitro* screening procedure to identify those compounds with potential anti-tumour activity.

We thank Dr Michael I. Sherman for his support and his comments on the manuscript, and Drs S Shapiro, P. Trown and M. Sellens for discussions. The unlabelled retinoids and ³H-retinoic acid were synthesised at Hoffmann-LaRoche, and provided by Drs B. Pawson and A. Liebman.

Folate deficiency and decreased brain 5-hydroxytryptamine synthesis in man and rat

FOLATE deficiency was once considered to belong exclusively to the field of haematology. However, recently there have been reports of neuropsychiatric symptoms in folate-deficient patients¹⁻⁴. Among the most frequent symptoms are mild polyneuropathies, fatigue, mild depression and abnormal intellectual functioning. These symptoms, which can occur in the absence of any severe haematological changes at routine haematological testing, are responsive to folate therapy. Excess folate can also produce undesirable side effects. One study on the effect of pharmacological doses of folate (15 mg daily) had to be abandoned after 1 month because of side effects such as altered sleep patterns, malaise, irritability and overactivity⁵; the

same clinical complaints were found in some of our patients who received folic acid therapy and in whom folate levels were very high (M. I. B., unpublished data). In studies on rats, behavioural deficits were found in animals fed diets that were either deficient⁶ or over-supplemented⁷ with folate. Both active and passive avoidance behaviour was affected. In this study we have looked for biochemical changes associated with folate deficiency and over-supplementation. Because the regional distribution of 5-methyltetrahydrofolate in the brain is similar to that of 5-hydroxytryptamine (5-HT)⁸ we looked at the latter. We found that the concentration of the 5-HT metabolite 5-hydroxyindoleacetic acid (5-HIAA) is low in the lumbar cerebrospinal fluid (CSF) of folate-deficient patients who have folate-responsive neuropsychiatric symptoms. We also found low brain 5-HT levels in the brains of rats fed folate-deficient or over-supplemented diets. Thus, there is a close association between folate-dependent behavioural effects and low brain 5-HT.

Table 1 gives CSF data for controls and for patients with folate deficiency. All the folate-deficient patients had neuropsychiatric symptoms such as mild polyneuropathies, fatigue and mild depression and were selected according to diagnostic criteria described previously^{2,3}. The folate deficiency was caused by a long-lasting folate-deficient diet with or without decreased absorption of folate due to gastrointestinal disorders. The low levels of 5-HIAA in the CSF of the folate-deficient patients were not due to deficiency of precursor for 5-HT synthesis, as CSF tryptophan, which to a certain extent reflects the brain level⁹, was normal.

In two previous studies, one on psychiatric patients¹⁰ and one on patients with senile dementia¹¹, folate deficiency was not found to be associated with low CSF 5-HIAA. In a third study, anticonvulsant treatment was found to be associated with low CSF folate and high CSF 5-HIAA¹². The high CSF 5-HIAA was probably due to increased precursor availability, as CSF tryptophan was also high. The elevated tryptophan and 5-HIAA levels were clearly associated with blood levels of anticonvulsants which were within or above the therapeutic range. In the first two of these studies, CSF folate was measured in groups of patients, who were then divided into normal and low-folate groups for comparison of CSF amine metabolite levels. In the third study, the patients were grouped according to whether or not they were on anticonvulsant medication. Low folate levels are not usually associated with neuropsychiatric symptoms which are responsive to folate therapy^{1,2} so it is unlikely that there were many patients in these studies with folate-responsive signs. On the other hand, in our study, where folate deficiency is associated with low CSF 5-HIAA, the low-folate patients were selected on the basis of behavioural and neurological symptoms which respond to folate administration. This suggests that low CSF 5-HIAA is associated not so much with folate deficiency itself as with neuropsychiatric effects of folate deficiency, which are responsive to folate therapy.

Table 1 Folate, tryptophan and 5-HIAA in controls and folate-deficient patients

		Controls		Folate-deficient patients		P
		Mean $\pm$ s.e.	n	Mean $\pm$ s.e.	n	
Serum folate (ng ml ⁻¹)	L. Casei method	7.48 $\pm$ 1.61	5	3.26 $\pm$ 0.73	6	<0.025
	Radioactive method	6.11 $\pm$ 0.51	9	2.41 $\pm$ 0.35	7	<0.005
CSF folate (ng ml ⁻¹)	L. Casei method	22.3 $\pm$ 1.9	9	11.3 $\pm$ 1.6	7	<0.005
	Radioactive method	19.7 $\pm$ 1.3	9	8.8 $\pm$ 1.3	7	<0.005
CSF tryptophan (ng ml ⁻¹)		362 $\pm$ 57	9	280 $\pm$ 61	7	NS
CSF 5-HIAA (ng ml ⁻¹)		20.9 $\pm$ 2.4	8	10.3 $\pm$ 2.3	7	<0.005

CSF was taken by lumbar puncture in a sitting position at 9.00 a.m. Controls were patients suffering from neuropsychiatric disorders not known to affect brain amine metabolism and who had CSF taken for diagnostic purposes. The characteristics of the folate-deficient patients are described in the text. There was no significant difference between the ages of the control patients (mean $\pm$ s.d. 38.6 $\pm$ 16.4 yr) and the folate-deficient patients (50.0 $\pm$ 10.1 yr). The methods for determination of folate have been described previously². Tryptophan and 5-HIAA in CSF were measured by the method of Anderson and Purdy¹⁹.

Brain amine levels in rats given folate-deficient or over-supplemented diets are given in Table 2. Experimental conditions were exactly the same as those in earlier experiments in which folate deficiency⁶ and over-supplementation⁷ were found to cause deficits in active and passive avoidance behaviour. In both groups, noradrenaline and dopamine were unchanged, whereas 5-HT was low. These data strengthen the association between alterations of behaviour and brain 5-HT in folate deficiency and suggest that excess folate may have biochemical effects that are in some respects similar.

The mechanism of the effect of folate on brain 5-HT metabolism is unknown. The fact that the distribution of 5-HT in brain is similar to that of 5-methyltetrahydrofolate⁸ suggests that a methylation reaction plays an important part, but in spite of the varied metabolic actions of folate in brain¹³ there are no methylation reactions known to alter the brain 5-HT content. However, there is one other possible mechanism that could be tested. In rats folate deficiency can induce thiamine deficiency¹⁴ and thiamine deficiency is frequently found in folate-depleted patients¹⁵. Recently, it has been shown that rats on a thiamine-deficient diet develop an impairment of the cerebellar 5-HT system¹⁶. Thus, the influence of folate deficiency on 5-HT may be mediated by thiamine deficiency. However, another mechanism must be invoked to explain the effects of excess folate. Here, one possibility is an effect on the functional activity of tryptophan hydroxylase, the rate-limiting enzyme in 5-HT synthesis; this enzyme requires tetrahydrobiopterin (BH₄) as cofactor. The last step in *de novo* synthesis of BH₄ is the reduction of BH₂ and this step is carried out by tetrahydrofolate reductase¹⁷. Excess folate might competitively inhibit this enzyme, thus preventing formation of new BH₄ and decreasing the activity of tryptophan hydroxylase.

Table 2 The effect of folate on rat brain biogenic amine content

Diet	5-HT	Dopamine	Noradrenaline
Purina	342 ± 11	897 ± 32	634 ± 35
Control (folate deficient + 2 µg folate per g diet)	346 ± 26	954 ± 36	623 ± 20
Folate deficient	242 ± 36*	945 ± 42	702 ± 37
Folate excess (folate deficient + 100 µg folate per g diet)	238 ± 36*	990 ± 37	672 ± 71

Charles River CD rats (60–70 g) were randomly divided into 4 groups and placed on the diets shown above for 3 weeks. To avoid diurnal changes in brain amine content the animals were all killed in the morning. Brain amine content was measured by liquid chromatography with electrochemical detection (S.N.Y., unpublished method). A brain extract was prepared according to the method of Ahtee *et al.*²⁰ except that the brains were homogenised in the presence of epinine, which was used as an internal standard. The sample preparation involves partial purification of the amines on a column of Amberlite CG 50. The amines are eluted from the column with 3 ml of 1.2 M HCl and 0.05 ml of the eluate was injected directly into the chromatograph (model LC-40; Bioanalytical Systems). Chromatography was carried out on a 2.1 mm × 50 cm column of VYDAC SCX pellicular resin with a buffer 50 mM in both acetate and citrate at pH 5.1. The amines were detected using a carbon paste electrode set at 0.8 V against the Ag/AgCl reference electrode. The amines were eluted in the order noradrenaline, dopamine, epinine, 5-HT. At a flow rate of 0.6 ml min⁻¹ each run took 20–25 min. All values are given as the mean of 10 determinations ± s.e. in ng ml⁻¹.

*Animals treated with diets containing no or excess folate have significantly less 5-HT than control animals ($P < 0.05$).

Although the mechanisms of these effects must remain speculative at the moment, we have shown that a vitamin deficiency can decrease synthesis of a neurotransmitter and influence behaviour in man. Folate deficiency and excess cause similar behavioural and biochemical changes in rats. In humans, the behavioural effects of these two conditions have some symptoms in common such as irritability and altered sleep patterns. Whether folate excess decreases brain 5-HT synthesis in man is unknown, but our data suggest that excess of even a water-

soluble vitamin such as folate can have detrimental effects. The data on folate deficiency is of interest in view of the relatively high incidence of folate deficiency in psychiatric patients¹⁸. In some patients decreased 5-HT levels due to folate deficiency may be an important cause of psychiatric symptoms.

This work was supported by grants MA-6065 and MA-5984 from the MRC of Canada and by a grant from the C.O. Monat Foundation. The folate-deficient diet was obtained from ICN.

Fibrin ϵ -(γ -glutamyl)lysine crosslink acceleration by red blood cells

FIBRIN, the skeletal protein of thrombi, is derived from its soluble plasma precursor, fibrinogen. Fibrinogen has a molecular weight of ~340,000. It is composed of three pairs of subunit polypeptide chains, A α , B β , and γ , of molecular weights 68,000, 56,000 and 49,000, respectively, joined by disulphide bonds. The serine protease thrombin releases fibrinopeptides A and B from the amino terminal end of the A α - and B β -chains of fibrinogen to leave the α - and β -chains of fibrin monomer. Fibrin monomers then align by noncovalent interactions to give a fibrin polymer gel. Under the influence of thrombin-activated factor XIII (factor XIIIa, activated fibrin stabilising factor, plasma transglutaminase) and calcium ion, covalent ϵ -(γ -glutamyl)lysine crosslinks are rapidly formed between γ -chains of adjacent fibrin monomers to give the γ -dimer subunit of partially crosslinked fibrin¹. The γ -crosslinking transforms the clot into a covalently bonded polymer, rendering it insoluble in 3 M urea and other agents that disrupt noncovalent interactions². Extensive crosslinking of the α -chain to give the α -polymer subunit of fully crosslinked fibrin requires several hours in plasma and confers relative plasmin resistance to the clot³. We report here an increased rate and extent of α -crosslinking when red blood cells are present in the fibrin clot.

Fresh whole blood was collected in a 9:1 dilution of 3.8% citrate and 1 M ϵ -aminocaproic acid (EACA). Red blood cells

Fig. 1 5% SDS-polyacrylamide gel electrophoresis of reduced samples of a time course fibrin crosslinking study of clots from plasma (a) whole blood (b) and plasma plus RBCs (c). Crosslinking of α -chain to form α -polymer (α p) is greater when RBCs are present in clot.

(RBCs) and plasma were separated by centrifugation and red cells were filtered through a 1:1 mixture of microcrystalline cellulose and α -cellulose to remove white cells and platelets⁴. The red cells were then washed 10 times in 5 volumes of 0.9% NaCl, pH 6.5. The washed red cells were added to platelet-poor plasma from which they were separated to give a final haematocrit of 40–50%. Aliquots of 200 μ l whole blood, 100 μ l platelet-poor plasma and 200 μ l RBCs plus platelet-poor plasma were added to separate sets of four 3 $\times$ 50 mm glass test tubes. EDTA was added to a final concentration of 1% in the first tube of each set to prevent fibrin crosslinking. The mixture was clotted with human thrombin (Fibrindex, Ortho Diagnostics, or ultrapure thrombin) at a final concentration of 5 NIH units per ml. The resulting fibrin clot from the plasma sample was wound on a glass micropipette to express serum from the clot. Serum and red cells were expressed from the red cell containing clots between layers of filter paper. Clots were then washed three times in distilled water, dropped into 200 μ l of a solution of 2% mercaptoethanol–2% SDS–8M urea–0.065M Tris-HCl, pH 7.4, and placed in a boiling water bath for 5 min to stop the reaction.

Additional samples in each set of tubes were clotted with thrombin in the presence of calcium (final concentration of thrombin and calcium, 5 NIH units per ml and 80 mM, respectively). Samples were incubated at room temperature for 5, 30 and 120 min to allow fibrin crosslinking to occur before the fibrin clots were separated and processed as described above. As earlier studies had shown complete γ -crosslinking by 5 min, samples clotted for 5 min or longer were washed in 3 M urea to enhance removal of plasma proteins and red cells from the fibrin mesh.

Analysis of reduced samples by SDS-polyacrylamide gel electrophoresis⁵ revealed complete γ -crosslinking in clots of blood, plasma and plasma plus red cells by 5 min. The α -chain of fibrin crosslinked much more rapidly and extensively in whole blood and in plasma plus red cells than in plasma alone (Fig. 1). Disappearance of the α -chain was associated with appearance of the α -polymer. The presence of 0.1 M EACA inhibited plasminogen activation to plasmin and there was no build up of α -chain degradation products with time.

Gels stained with Coomassie brilliant blue were scanned using a Gelman ACD-15 densitometer. Areas under scans of the α -chain were compared with the sums of the areas under scans of the γ -chain, β -chain and γ -dimer to give a ratio (termed the α -ratio) of free α -chain to the sum of other fibrin chains. The α -ratio was plotted against time to quantitate the rate of disappearance of α -crosslinking. Such plots demonstrated that even extensively washed RBCs accelerated fibrin α -crosslinking in platelet-poor plasma to a rate and extent similar to that in whole blood.

To determine whether platelet factor XIII activity accelerated fibrin crosslinking in plasma, crosslinking studies were done as described above using platelet-rich and platelet-poor plasma. The rate and extent of fibrin α -crosslinking were not significantly different in platelet-rich and platelet-poor plasma.

In one of a series of studies designed to determine whether the release of intrinsic transglutaminase⁶ or other intracellular substance from red cells during clotting might be responsible for accelerated fibrin crosslinking, washed red cells were treated with *p*-hydroxymercuribenzoate (PMB) to block the sulphhydryl groups on their cell surface. Red cells were incubated in 5 volumes of 10 mM PMB in 0.9% NaCl, pH 6.5, for 20 min, and then washed three times to remove excess PMB. When these red cells were resuspended in plasma, they no longer accelerated the α -crosslinking of fibrin (Fig. 2). As PMB does not cross intact red cell membranes⁷, the crosslink-accelerating activity of RBCs must reside in or on the external surface of the cell membrane and be independent of intrinsic transglutaminase activity.

To further define the activity of red cell membranes in fibrin crosslinking, erythrocyte ghosts were prepared and their ability to accelerate fibrin crosslinking in plasma was determined. Erythrocyte ghosts prepared by hypotonic lysis⁸ did not accelerate fibrin crosslinking. As the fibrin crosslink accelerating activity of red cells was not diminished significantly by extensive washing in 0.9% NaCl, but was lost from hypotonically prepared red cell membranes, the activity must be due to a substance in or on the membranes that is inactivated or released by hypotonic media.

Additional experiments failed to relate intracellular red cell constituents to the acceleration of fibrin crosslinking by red cells. Glutathione in final concentrations of 1 mM, 3 mM and 10 mM had negligible effects on the rate of fibrin crosslinking in plasma

Fig. 2 Rate and extent of disappearance of α -chain in clots of plasma (□) plasma plus RBCs (○) and plasma plus *p*-hydroxymercuribenzoate-treated RBCs (■). The α -ratio reflects disappearance of free α -chain as this is crosslinked to form the α -polymer.

when compared with the effects of intact RBCs. The supernatant from red cell membrane ghost preparations also failed to accelerate fibrin crosslinking in plasma to the same extent as intact red cells. Generally, no difference in the rate and extent of crosslinking was observed, although some samples showed minimal (<10%) acceleration of crosslinking.

Because of the rapid rate of formation of γ -crosslinks, the effect of red cells on the rate of that reaction could not be adequately assessed. When the rate of crosslinking of the γ -chain of fibrin was evaluated at 4 °C in plasma and in whole blood the reaction was still virtually complete at 5 min and no significant differences in the rate could be determined.

Our data are most consistent with the presence of a sulphhydryl-containing membrane protein located in or on the external surface of red cells that accelerates fibrin crosslinking. RBCs may thus have a more important physiological role in the acceleration of fibrin crosslinking and stabilisation of thrombi than previously recognised. Conclusions about *in vivo* fibrin crosslinking derived from studies of clotted plasma or fibrinogen may be misleading because of the absence of RBCs in such coagulum.

We thank Lani Bernier and Wilda Conyers for technical assistance and Dr D. L. Aronson for ultrapure thrombin.

Viroid replication is inhibited by α -amanitin

VIROIDS are infectious single-stranded circular RNA molecules¹ which cause disease in higher plants. Although the complete molecular structure of one viroid has recently been established², the mechanism of viroid replication and pathogenesis is still unknown. The viroid molecule carries insufficient genetic information to code for a complete viroid-specified replicase. Replication must therefore depend on host cell enzymes. We report here the inhibition by α -amanitin, of ³H-uridine incorporation into viroid RNA in infected tomato protoplasts. The inhibitory intracellular concentrations of α -amanitin which we determined suggest the involvement of the nuclear DNA-dependent RNA polymerase II in viroid replication.

Healthy plant cells contain two types of known RNA-synthesising enzymes, namely the DNA-dependent RNA polymerase system³ and the recently described RNA-dependent RNA replicase system^{4,5}. Viroids could therefore either be replicated through complementary RNA, as are most RNA viruses, or through a DNA template. This DNA template could be already present in the host cell in a repressed state or could be

Fig. 1 Analysis of 2 M LiCl-soluble RNA from CPFV-infected tomato protoplasts in 5% polyacrylamide gel. Protoplasts were isolated from green leaves of the tomato cultivar 'Hilda 72' with the aid of Macerozyme R-10 and cellulase 'Onozuka R-10' at pH 7.0 and inoculated with 100 μ g purified CPFV in 10 ml glycine-KOH-buffered mannitol at pH 9 containing up to 5×10^7 protoplasts¹⁰. After inoculation, protoplasts were cultured at a cell density of 2×10^5 ml⁻¹ at 29 °C in the dark. ³H-Uridine (10 μ Ci ml⁻¹) was added at the beginning of the culture period. 48 h after inoculation one-third of the protoplasts was collected by centrifugation, shock-frozen with liquid nitrogen and stored at -80 °C until RNA extraction. To one-half of the remaining protoplast suspension α -amanitin (dissolved in culture medium) was added to give a final concentration of 50 μ g ml⁻¹. An equal volume of culture medium without α -amanitin was added to the other half of the protoplast suspension. 72 h after inoculation, that is, 24 h in the presence of α -amanitin, all protoplasts were collected and frozen. RNA was extracted from these samples with the aid of phenol-SDS and salt-fractionated with 2 M LiCl⁸. RNA soluble in 2 M LiCl was dissolved in 200 μ l buffer containing 8 M urea and aliquots of 50 μ l RNA were analysed by electrophoresis on 16 cm long cylindrical 5% polyacrylamide gels. 0.1 A₂₆₀ of purified CPFV was added as marker and the gels were run at 1 mA per gel for 12 h at 7 °C. After electrophoresis gels were stained with methylene blue, destained in 7% acetic acid, cut into 1 mm slices and counted for ³H radioactivity. **a**, RNA profile 72 h after inoculation and culture without α -amanitin. **b**, RNA profile 72 h after inoculation, but cultured in the presence of 50 μ g α -amanitin per ml culture medium during the period 48-72 h after inoculation. The control data of ³H-incorporation into RNA between 0 and 48 h are given in Table 1.

newly synthesised on viroid infection. Previous studies with actinomycin D, which inhibits DNA-dependent RNA transcription, applied to leaf strips⁶ and nuclei⁷ prepared from viroid-infected tomato leaves indicated that viroid replication was unlikely to proceed through an RNA-dependent RNA replicase.

Tomato protoplasts isolated from green leaves of the tomato cultivar 'Hilda 72' as previously described⁸ were used. They regenerate new cell walls after 3 days⁹ and divide within a week (unpublished results). Their general metabolic capacity is substantiated by their ability to produce complete tobacco mosaic virus (TMV) particles after infection with TMV RNA *in vitro*⁹. In these protoplasts viroid replication has been followed by ³H-uridine incorporation after infection *in vitro*¹⁰. Freshly

Fig. 2 Intracellular concentration of ³H-α-amanitin in tomato protoplasts. Protoplasts were isolated and cultured as described for Fig. 1. ³H-O-methyl-dehydroxymethyl-α-amanitin (specific activity 2 Ci mmol⁻¹) was added to protoplast suspensions to a final concentration of 5 µg ml⁻¹ (~10⁻⁶ M) (O) and 50 µg ml⁻¹ (~10⁻⁵ M) (●). At 0, 2, 10 and 20 h of incubation with ³H-α-amanitin aliquots were collected, washed four times with culture medium, digested with Soluene (Packard) and counted for ³H radioactivity. Quench corrections were performed in parallel experiments with equal numbers of protoplasts using ³H toluene as standard.

isolated protoplasts were inoculated with cucumber pale fruit viroid (CPFV)¹¹ and cultured as previously described¹⁰. Control experiments comparing the effect of α-amanitin on TMV replication (which proceeds through an RNA-dependent RNA-replicase) were carried out on protoplasts of the same batch after inoculation with TMV RNA according to our published procedure⁹. Biosynthesis of cellular RNA, TMV RNA and viroid was measured by incorporation of ³H uridine into these RNA species, which were separated on 2.5% and 5% polyacrylamide gels¹⁰ after extraction with phenol-SDS and salt fractionation⁸.

To discriminate clearly between the different DNA-dependent RNA polymerases possibly involved in viroid replication, we applied α-amanitin to our protoplast system. In eukaryotic cells α-amanitin selectively inhibits the DNA-dependent RNA polymerases II and III at low and high concentrations, respectively, whereas RNA polymerase I is not inhibited¹²⁻¹⁵. As shown in Table 1 α-amanitin has no appreciable effect on the biosynthesis of cellular RNA and viroid if present at a concentration of 10 µg ml⁻¹ during the period 48–72 h after inoculation, when viroid replication is detectably increased¹⁰. With 50 µg ml⁻¹ α-amanitin, viroid replication is inhibited to ~75%, whereas the biosynthesis of tRNA, 5S RNA, 7S RNA and rRNA is again not appreciably affected (Fig. 1 and Table 1). We wish to point out that our protoplasts are killed by this concen-

tration of α-amanitin if present throughout the total time of culture. Therefore, only the brief exposure of protoplasts to this drug described above gives meaningful results. The RNA profile of uninfected protoplasts, where the viroid peak is naturally lacking, shows a similar effect of α-amanitin on the cellular RNA species.

In view of the concentration-dependent specificity of α-amanitin inhibition of RNA polymerases the interpretation of such *in vivo* experiments depends on knowing the intracellular concentration of this inhibitor. We therefore determined its intracellular concentration in our experimental conditions using a ³H-labelled amanitin¹⁶. When tomato protoplasts were exposed to 10⁻⁵ M (50 µg ml⁻¹) and 10⁻⁶ M (5 µg ml⁻¹) ³H-α-amanitin for 20 h, an intracellular concentration of 2 × 10⁻⁸ M and 2 × 10⁻⁹ M, respectively, was already reached within the first 10 h incubation (Fig. 2). This clearly demonstrates that the intracellular concentration of α-amanitin is in the range of 10⁻⁸ M in the conditions in which viroid replication is inhibited, namely at 50 µg α-amanitin per ml culture medium. *In vitro* experiments with DNA-dependent RNA polymerases isolated from different sources¹⁴ including higher plants³ have shown that RNA polymerase II is, in fact, specifically inhibited at a concentration of 10⁻⁸ M α-amanitin, whereas inhibition of RNA polymerase III requires a 1,000-fold higher concentration¹⁵. Studies with animal^{17,18} and plant^{19,20} cells have shown that in comparable experimental conditions RNA polymerase II is also inhibited *in vivo*. As the intracellular concentration of α-amanitin which inhibits ³H uridine incorporation into viroid RNA in our protoplasts is in the range where the nuclear DNA-dependent RNA polymerase II is specifically inhibited, we suggest that this enzyme system is involved in viroid replication.

Control experiments using tomato protoplasts inoculated with TMV RNA revealed that replication and accumulation of complete TMV was not affected, when α-amanitin was present at a concentration of 50 µg ml⁻¹ during the period 24–48 h after inoculation, where TMV replication is known to increase logarithmically in our system (unpublished results). Therefore, the marked inhibition of viroid replication by α-amanitin is unlikely to be due to a secondary effect of this drug on cell metabolism in general.

For comparison, we also investigated the effect of actinomycin D on the DNA-dependent RNA metabolism in CPFV-infected protoplasts. As viroid replication in tomato protoplasts is known to increase to a detectable level 48–72 h after *in vitro* inoculation¹⁰, the inhibitor was applied so that it was present during this period. Actinomycin D at a concentration of 20 µg ml⁻¹ culture medium inhibits total RNA biosynthesis up to ~80% (Table 2) which agrees with previous protoplast work²¹. The detailed analysis showed that viroid replication is inhibited to about the same degree (~85%) as the synthesis of cellular RNA. Identical results were obtained in control experiments with uninfected tomato protoplasts, the RNA profile of which differs only by lacking the peak representing ³H-labelled viroid. From comparable results previously obtained with leaf disks⁶ and

Table 1 Effect of α-amanitin on RNA biosynthesis in viroid-infected tomato protoplasts

The figures are derived from experiments as described for Fig. 1. D.p.m. values given for total RNA and for each of the prominent RNA species indicate the incorporation of ³H uridine into the RNA species during the period 48–72 h after inoculation, where α-amanitin was present. This net incorporation was calculated on the basis of the d.p.m. values of the ³H-incorporation into RNA between 0 and 48 h after inoculation (control 0–48 h).

Protoplasts were inoculated with CPFV and cultured for 48 h as described for Fig. 1. At that time aliquots of the protoplast suspensions were collected by centrifugation and frozen. Actinomycin D or cycloheximide were added to remaining aliquots of the protoplast suspension to give the final concentrations as indicated. 72 h after inoculation, that is, 24 h in the presence of actinomycin D or cycloheximide, protoplasts were collected, RNA was extracted and analysed on 5% polyacrylamide gels. The data given show the [^3H]uridine incorporation into total RNA and into the different RNA species during the period 48-72 h after inoculation. This net incorporation was calculated on the basis of the d.p.m. values of the [^3H] incorporation into RNA between 0 and 48 h after inoculation (control 0-48 h).

nuclei⁷ from viroid-infected tomato leaves, the involvement of host DNA during viroid replication was inferred. However, as actinomycin D inhibits the biosynthesis of all RNA species including viroid RNA, a nonspecific secondary effect of this inhibitor cannot be ruled out completely. Therefore, we can exclude only the involvement of pre-existing RNA-dependent RNA replicases during viroid replication. These are actinomycin D resistant as demonstrated in several systems infected with conventional RNA plant viruses²¹⁻²³.

Finally, we studied the effect of cycloheximide on RNA synthesis to test the possible requirement of newly synthesised proteins for viroid replication. When cycloheximide is applied to CPFV-infected protoplasts in the range from 1 to 50 $\mu\text{g ml}^{-1}$ in exactly the same conditions as actinomycin D (Table 2), the biosynthesis of cellular and viroid RNA is strongly inhibited although cycloheximide is known to interfere specifically only with protein biosynthesis and not with nucleic acid transcription itself. Similar results are obtained with uninfected protoplasts. These results do not allow us to conclude that specific and newly synthesised proteins are a prerequisite for viroid replication, because cycloheximide exerts a nonspecific and rather general disturbance of cell metabolism.

The specific inhibition of [^3H] uridine incorporation into viroid RNA by an intracellular concentration of 10^{-6} M α -amanitin strongly suggests that DNA-dependent RNA polymerase II is involved in viroid replication. In these conditions the biosynthesis of the prominent cellular RNA species (rRNA, 7S RNA, 5S RNA and tRNA) is hardly affected. RNA polymerase II is located in the nucleoplasm and is responsible only for the transcription of heterogeneous nuclear RNA species from the corresponding sections of the cellular DNA genome^{13,15}. Our assumption that the nuclear RNA polymerase II is involved in viroid replication is supported by earlier findings^{24,25} that the bulk of viroid infectivity is closely associated with nuclei and chromatin. Our present inhibition studies could explain the identical location of RNA polymerase II and of the accumulated viroid RNA as one of its possible products. The sensitivity of viroid replication to actinomycin D agrees with this conclusion irrespective of whether it is directly affecting a possible viroid-specific DNA template or is inhibiting DNA-dependent RNA biosynthesis in general.

The DNA dependence of viroid RNA replication has previously been postulated from hybridisation experiments with [^{125}I]-labelled viroid RNA from which the existence of cellular DNA sequences complementary to viroid RNA in viroid-infected^{26,27} and even in healthy²⁷ host plant species was inferred. On the other hand, from a similar experimental approach viroid replication involving a complementary RNA was assumed²⁴. However, these conventional hybridisation experiments must be interpreted cautiously for the following reasons. The circularity and high degree of self-complementarity of the viroid molecule^{1,2}, require very specific experimental conditions to obtain reliable hybridisation data. Further-

more, the absence of any trace of contaminating cellular RNA species in the viroid probes used for hybridisation must be rigorously demonstrated by appropriate controls and by fingerprint analysis²⁹.

We emphasise that we do not regard the observed α -amanitin inhibition as definitive proof of direct replication of viroid RNA by the nuclear DNA-dependent RNA polymerase II. There are several possible mechanisms by which this enzyme system could be indirectly involved as a result of its central role in the formation of mRNAs in the host cell. There is also the remote possibility that viroid replication may proceed through a yet unknown pathway which is α -amanitin sensitive. If, however, DNA-dependent RNA polymerase II is directly involved it still remains to be determined whether viroid replication is based on derepression of a pre-existing viroid-specific DNA template or whether the infecting viroid molecule, because of its DNA-like secondary structure, is accepted directly as a template by DNA-dependent RNA polymerase II. The circularity and the unique secondary structure, which are a common feature of all viroids³⁰, are most probably of functional importance, and may add to the complexity of their replicating mechanism. For its elucidation, *in vitro* studies with appropriate enzymes, particularly of host plant origin, seem to be essential.

Crystal structure of a eukaryotic initiator tRNA

OUR understanding of the molecular structure–function relationship in tRNA rests mainly on three types of information. First, on the common sequence patterns which have emerged from careful examination of many primary structures^{1–3}; second, a wide variety of spectral and other physical and chemical results must be accounted for by the molecular structure^{4–6}; and third, there is the detailed image of the yeast tRNA^{Phe} molecule independently determined and refined from two different—albeit similar—crystal forms^{7–10}. It is also clear, however, that the molecular model deduced from the yeast tRNA^{Phe} crystal structure cannot be easily reconciled with all structural requirements for function and is best considered a well-defined and stable canonical form of tRNA which is packed in an unusually well-ordered way in specific crystal lattices. Notwithstanding the enormous value of this canonical form in explaining the basic architectural features of tRNA, it is clearly important to image other crystalline tRNAs; particularly tRNAs that exhibit different functions (such as, initiators) or have significantly different covalent structures (for example, class III tRNAs)¹ or those that crystallise in different solvent conditions. We report here the initial results of the crystal structure determination of a eukaryotic initiator tRNA crystallised from a highly polar aqueous solvent^{11,12}. Its architecture is essentially the same as crystalline yeast tRNA^{Phe}, except for a small but significant difference in the position of the anticodon arm.

Our interpretation is based on a 4.5 Å electron density map prepared by the method of multiple isomorphous replacement (MIR) and augmented by direct methods¹³. The trace of the sugar–phosphate backbone is further constrained by four heavy-atom markers, each covalently linked to a specific residue and an elaborate network of crystallographic dyads upon which the

Fig. 1 Phasing power $(\sum |F_H|^2)^{1/2} / (\sum (|F_{PH}^{obs}| - |F_{PH}^{calc}|)^2)^{1/2}$ of five isomorphous derivatives plotted against resolution. They are gadolinium, lightly substituted, precession data (■); gadolinium, heavily substituted, precession data (□); gadolinium, oscillation data (△); pyridyl mercury acetate, precession data (●), and pyridyl mercury acetate, oscillation data (○). Figure of merit (---) is determined from MIR phasing³³ and has a mean value of 0.49 for all reflections to 4.5 Å resolution. F_H is the calculated heavy atom structure amplitude; $(|F_{PH}^{obs}| - |F_{PH}^{calc}|)$ is the 'lack of closure' error between observed and calculated isomorphous derivative structure amplitudes.

Fig. 2 Comparison of 10 sections of the 4.5 Å map of yeast tRNA^{Met} before (above) and after (below) the inclusion of 28 intense low resolution terms determined by matricial phase predictions. Both maps are contoured at the same intervals. Density cleared by this technique was ultimately shown to be noise, while density that was enhanced improved connectivity in the helical stems. Density on the dyad axes diminished.

molecule cannot intrude. The model presented here is based on a low resolution least-squares refinement procedure which assumes that the molecule is organised in four domains corresponding to the arms of the cloverleaf hydrogen-bonding pattern¹⁴.

The crystals have three important characteristics¹⁵. (1) They are grown from and stabilised in approximately 2M (NH₄)₂SO₄ containing 5 mM Mg²⁺ and 2 mM spermine and no organic solvent. The 2M ammonium ion may alter the structural role attributed to Mg²⁺ and spermine in crystalline yeast tRNA^{Phe} (refs 16–18). (2) Only 17.5% of the crystal volume is occupied by tRNA. Treating the remaining 82.5% as disordered solvent of uniform density was quite helpful in the structure analysis. (3) The crystal is poorly ordered, making accurate data collection very difficult and effectively impossible beyond 4 Å resolution. Data for the parent and three isomorphous heavy atom derivatives were collected initially to 6 Å by procession photography and extended to 4.0 Å by oscillation photographs in which a single crystal was devoted to each of ~30 overlapping 2.5° or 2° sectors. Figure 1 shows that there is useful phasing power in the best derivative to about 4.5 Å resolution. Schevitz *et al.*¹⁵ presented a 6 Å analysis of the yeast tRNA^{Met} crystal structure. Despite two heavy atom markers at iodine ⁵C₇₃ (5-bonding onto cytosine at residue 73) and osmium ^{5,6}C₃₈ the electron density could not be convincingly interpreted in terms of the molecular backbone. Even when the data for the parent structure and MIR

Fig. 3 Final phase change in degrees resulting from direct methods (see text) as a function of the original figure of merit determined by conventional MIR phasing. Phase information from both sources was merged by multiplying together their respective phase probability curves after each cycle of combined solvent levelling and density modification. Note that those reflections predicted to have a high reliability by MIR phasing (figure of merit near 1.0) remained closely tethered to their MIR phase while those with a low MIR reliability (figure of merit near 0) tend to be more easily shifted toward phases calculated by direct methods.

phases were extended to 4.5 Å resolution and a third heavy atom marker at iodine ^{127}I was used the map was still too 'noisy' to interpret confidently.

One particularly vexing deficiency in the MIR map was the inability to define the exact molecular boundary with

confidence. As over 80% of the unit cell volume was solvent this structure was particularly amenable to phase improvement by solvent levelling if the molecular boundary could be accurately established^{19,20}. The boundary was established by phasing the previously omitted very intense inner reflections ($d > 14$ Å). In the effort to secure high resolution data by extensively irradiating each crystal, these strong reflections were overexposed and far exceeded the dynamic range of even the most weakly exposed film. Even if relatively accurate amplitudes had been obtained for the parent and derivatives it is likely that the heavy atom contribution would not have been strong enough to provide accurate difference amplitudes to phase the very strongest of these reflections. To circumvent this problem the inner core of intense parent intensities was accurately remeasured and the phases of 28 of the very strongest reflections were determined by applying matricial methods to the amplitudes and MIR phases of 107 known reflections. The technique is similar to that used by Podjarny *et al.* to extend the phases of tricornic lysine²¹ and yeast tRNA^{Phe} (ref. 22) to a higher resolution than the starting phase set. Here the procedure was used to extend phases to a lower resolution than the MIR phase set. The details of this work will be published elsewhere¹³; however, it is evident from Fig. 2 that there was substantial enhancement of the contrast between the molecule and the solvent. The improved map enabled us to confidently define 65% of the unit cell as solvent. New phases were calculated from a map in which the noise in the 'solvent' was levelled to a uniform average value and negative regions in the molecule attenuated^{23,24}. These phases were merged with

Fig. 4 Comparison of the yeast tRNA^{Met} (heavy line) and yeast tRNA^{Phe} (light line) structures in two stereo views. The phosphate backbone is shown with every tenth phosphate residue of yeast tRNA^{Met} numbered.

MIR phases and the 'density modification' procedure repeated for three cycles. Figure 3 shows that the phase improvement effected by density modification was most apparent for those reflections whose MIR phase was, in general, least accurate.

Four residues have been reacted stoichiometrically with covalently bonded heavy atoms. The heavy-atom markers were nicely distributed along the molecular backbone and provided a clear guide to the interpretation. (1) Iodine $^{57}\text{C}_{73}$: the third residue from the 3' terminus was labelled with iodine either by enzymatically rebuilding the 3' terminus with iodine ^{57}CTP and nucleotidyl transferase²⁵ or by directly iodinating the crystals²⁶. (2) iodine $^{57}\text{C}_{74}$: direct iodination also labels C_{74} which shows a small peak that cannot be refined, presumably because of disorder. (3) Iodine $^{57}\text{U}_8$: produced by direct iodination of the crystal²⁶. (4) Osmium $^{195}\text{C}_{38}$: direct reaction of the crystals with Os(VI) and pyridine²⁷ forming a 5,6-bispyridyl osmate diester^{28,29} with C_{38} (ref. 30).

Initially we interpreted the map with a conventional optical comparator and skeletal models, but it was found more convenient to use computerised 'static' molecular graphics³¹ to search for significantly different orientations of the stable helical substructures operating within the constraints imposed by the heavy atom markers and the crystallographic dyad axes upon which the model could not intrude. Subsequently, a residue-by-residue computerised fit of the entire model to the map was attempted in 'real time' at the Computer Graphics Laboratory at the University of North Carolina and this allowed us to rule out additional alternatives; however, we found the map was not sufficiently well resolved to impose a correspondence between phosphate, ribose and base moieties in the model and the peaks in the electron density.

The coordinates of the optimal fit were used as guides to position a tRNA^{Phe} model¹⁰ in the P6_422 unit cell. The root-mean-square deviation between the guide points and the tRNA^{Phe} model coordinates was 5.4 Å. This model was divided into four rigid groups corresponding to the helical arms and refined against observed intensities using a least squares procedure (CORELS) of Sussman *et al.*³² that 'restrained' the helical arms to remain within reasonable bonding distance of each other. The refinement was started at 12.5 Å and carried to 6 Å. The final crystallographic *R* factor between calculated and observed data to 6 Å was 42.3%; to 12 Å, 33%. These values indicate an essentially correct interpretation of a macromolecular crystal structure.

The molecular structure is shown in Fig. 4 contrasted with that of yeast tRNA^{Phe} . Except for a small region near the anticodon stem, the model accounts for virtually all the electron density in terms of a dominant sugar phosphate backbone. At this stage of the analysis the molecular architecture is generally similar to that of yeast tRNA^{Phe} .

The position of the anticodon arm in the crystal structure of yeast tRNA^{Met} differs significantly from the crystal structure of yeast tRNA^{Phe} (Fig. 4). Moreover, the refinement parameters show that although the anticodon arm converges to the position shown in Figure 4, it is the most poorly localised segment of the crystal structure. These observations suggest that the orientation of the anticodon arm is not rigidly fixed and the union of the D and anticodon stems may, as suggested previously^{18,34}, serve as a hinge point to allow alterations in the orientation of the anticodon during functional adjustments of the structure. Except for the possible stacking of a non Watson-Crick pair m^2G_{26} and A_{44} , no stabilising tertiary interaction can be invoked to ensure a particular orientation of the anticodon arm.

The molecules are packed with all 12 of the acceptor-T helices in the unit cell clustered around the 6_4 axis at an angle of approximately 20°. Pairs of neighbouring molecules that have opposing acceptor stems stack upon one another roughly in helical register. This explains the intense continuous helical diffraction pattern along c^* observed at approximately 3 Å resolution, well beyond the lattice transform¹⁵.

The anticodon arms project out roughly perpendicular to the 6_4 axes and contact neighbouring molecules at their anticodon

loop and the base of the D-stem. Thus many of the stabilising interactions involve the anticodon arm, which we believe to be extended on a flexible hinge. The fact that the lattice is connected through these hinged anticodon arms may be the reason that this (and possibly many other) tRNA crystals, although readily grown, are poorly ordered. The situation is reminiscent of the characteristically poorly ordered crystalline immunoglobulins³⁵—another macromolecule where flexibly hinged domains may be necessary for function.

R.W.S. was a fellow of the American Cancer Society, Damon Runyon/Walter Winchell Foundation, and USPHS. A.D.P. is a fellow of the Damon Runyon/Walter Winchell Foundation; NK was a fellow of USPHS, and J.J.H. was a USPHS trainee. This work was supported by grants from the NSF, USPHS, and American Cancer Society. The Weizmann Institute Computer Center provided computer facilities.

Note added in proof: Refinement with a more flexible model has reduced the crystallographic *R*-factor to 25% for all data to 4.0 Å resolution. Difference maps are clean and tertiary structural interactions are seen which can be correlated to those in crystalline yeast tRNA^{Phe} .

A high molecular weight form of terminal deoxynucleotidyl transferase

CALF thymus terminal deoxynucleotidyl transferase (TdT) (EC 2.7.7.31) is a low molecular weight protein containing two peptides of MWs 24,000 and 8,000 in a native structure estimated to have a molecular weight of 32,000 (ref. 1). Use of antibody directed against homogeneous bovine transferase² for immunofluorescent cytology showed the normal thymus localisation to be cytoplasmic and nuclear, whereas bone marrow localisation is only nuclear³. Several human lymphoblastoid cell lines that contain terminal transferase activity also exhibit the nuclear location by immunofluorescence⁴. As cultured lymphoblastoid cell lines are readily labelled with radioactive amino acids we surveyed the peptides present in the immunoprecipitated transferase from these lines by fluorography of SDS gels. The results presented here show that a single 58,000-MW peptide is precipitated by monospecific rabbit antibody against bovine transferase. No peptides as small as those peptides present in calf thymus transferase were detected.

Our experiments used several lymphoblastoid cell lines. Line 8402 (ref. 5) contains >90% TdT⁺ cells and exhibits around 325 units of transferase per 10⁸ cells. Line 8392 (ref. 5), originating from the same patient, is completely negative by TdT immunofluorescence and enzyme assay. Line CEM-CCRF (ref. 6) contains about 19 units of enzyme per 10⁸ cells and has ~9% TdT⁺ cells. We cloned this line to produce CEM-clone 10 (>90% TdT⁺ cells, 280 units per 10⁸ cells) and CEM-clone 23 (<2% TdT⁺ cells, ~4 units per 10⁸ cells). All of these lines were grown in RPMI-1640 medium containing 10% fetal calf serum in spinner bottles at 37 °C. All have generation times of ~24 h in these conditions.

The human lymphoblastoid cells were labelled to high specific activity (about 60,000 c.p.m. per µg protein) by replacing the leucine and isoleucine in the medium with the corresponding ³H-amino acids. Cells were allowed to incorporate amino acids for 24 h and then extracts of the washed cells were prepared by sonication in 0.25 M potassium phosphate buffer at pH 7.5. The final cell extract is the supernatant fraction obtained after centrifugation at 100,000g for 1 h. Washed immunoprecipitates prepared from these cell extracts (see legend to Fig. 1) and separated on SDS-acrylamide gels produced the fluorograms shown in Fig. 1.

The results clearly demonstrate that a single radioactive protein is found in the immunoprecipitate from lines 8402 and CEM-clone 10 (Fig. 1, a' and b'). The MW of this peptide is estimated to be 58,000. No radioactive peptides were obtained from TdT-negative lines such as line 8392 (Fig. 1, c') and negative clones such as line CEM-clone 23 (Fig. 1, d'). Positive lines regularly contained the 58,000-MW peptide and we conclude that this is a high MW form of human TdT. Mouse line P-1798 and human line NALM-1 (also TdT⁺) also contain the 58,000-MW peptide (data not shown).

The specificity of each of the antibody reagents used was carefully checked, and no nonspecific contaminants were found. This is demonstrated by the absence of bands in the transferase negative lines (Fig. 1, c' and d'). Our first experiments (not shown here) used a secondary goat (IgG) anti-rabbit IgG for complete precipitation of the rabbit anti-transferase-transferase complex and a large excess of goat heavy chain was therefore present on the SDS gel near the TdT peptide band. Although common practice indicates that this excess of high MW peptides does not affect migration of lower MW species, we reduced the amount of goat heavy-chain peptide on the gel by using the F(ab')₂ of goat IgG as the secondary antibody in the experiments presented in Fig. 1. The position of the 58,000-MW peptide is unchanged on SDS gels of the F(ab')₂ precipitated complexes. The radioactive band migrates slightly more slowly than the rabbit heavy chain arising from the primary antibody (Fig. 1, a, b, c and d), and the goat heavy-chain fragments

Fig. 1 Fluorogram of SDS-polyacrylamide gel of immunoprecipitated terminal transferase. Extracts of human lymphoblastoid cells labelled with ³H-leucine and ³H-isoleucine were precipitated with rabbit anti-bovine terminal transferase (0.36 mg ml⁻¹) purified by immunoabsorbent chromatography³ followed by F(ab')₂ goat anti-rabbit IgG (5 mg ml⁻¹). The immunoprecipitates were washed 4 times in Tris-Cl buffered saline, pH 7.2, and twice in Tris-Cl buffered saline containing 0.5% Triton X-100, 0.5% deoxycholate, 20 mM leucine, 20 mM isoleucine. The precipitates were resuspended for the final two washes by sonication. The washed precipitates were dissolved in sample buffer (62.5 mM Tris-HCl, pH 6.8, 2% SDS, 10% glycerol, 0.001% bromophenol blue, 5% 2-mercaptoethanol), heated for 1 h at 100 °C, and analysed on 16% SDS slab gels. Electrophoresis was carried out as described by Laemmli⁷. Gels were stained in Coomassie blue and processed for fluorography⁸. The position of MW markers and the α and β chains of calf thymus transferase are indicated by arrows. Lanes a, b, c, d, total protein in immunoprecipitates from line 8402, line CEM-clone 10, line 8392, and line CEM-clone 23, respectively (Coomassie stain). a', b', c', d', radioactivity from immunoprecipitates of line 8402, line CEM-clone 10, line 8392, and line CEM-clone 23, respectively. Peptide markers were bovine serum albumin (BSA, MW 67,000 67 K), human IgG (IgG, MW 55,000, γ chain), ovalbumin (OVAL, MW 45,000 45 K), calf thymus terminal transferase (THY-TdT-β and THY-TdT-α) and myoglobin (MYO, MW 17,800 17.8 K). The apparent MWs for TdT peptides in this gel system are 26,000 and 10,000.

migrate to the 24,000-MW region. Addition of pure bovine enzyme to the extract before addition of antibodies effectively competes with precipitation of radioactive protein. We conclude that the overwhelming majority of radioactivity in the immunoprecipitate has determinants related to the bovine enzyme.

The original work on rabbit anti-TdT demonstrated neutralisation of enzyme activity when the Ab-Ag mixture was assayed with d(pA)₅₀ and ³H-dGTP (ref. 2). A footnote suggested, however, that the immune precipitates could be demonstrated to contain enzyme activity. This was done by using an assay mixture containing d(pT)₃ and ³H-dATP to test for enzyme activity in the isolated immunoprecipitate. The small size of the initiator presumably permits diffusion into the immune complex and allows detection of enzyme activity at a level of around 10% of the free enzyme. We analysed enzyme activity in non-radioactive precipitates (requiring no background subtractions) and radioactive precipitates (which require rather large background subtraction) from line 8402 extracts and calculated that essentially all of the activity present in the original extract is present in the precipitate. We conclude that the 58,000-MW band on the SDS gels is responsible for the enzyme activity as no other bands are seen, and the precipitate is enzymatically active. The antibody procedure precipitates about 0.05–0.10 µg of protein from the crude extracts that contain

transferase activity, corresponding to 0.02–0.05% of the total cell protein added in the precipitation mixture. This amount of protein precipitate is also consistent with the level of enzyme protein estimated to be present in the extracts.

The existence of a high MW form of transferase in the malignant cell lines examined in this survey is a novel finding. Unfortunately this finding cannot be used to explain the multiplicity of forms observed by phosphocellulose chromatography of crude extracts^{9,10} of other tissues for the following reasons: Both line 8402 and CEM-clone 10 exhibit two distinct enzyme activity peaks on phosphocellulose (Hassur, Chang and F.J.B., unpublished results) but only a single peptide is seen on the fluorograms in Fig. 1; both enzyme peaks are inhibited by anti-TdT. The existence of several ionic forms of transferase in a single MW species requires an explanation based on amino acid changes or other ionic substitutions. Similarly, several isoelectric species can be demonstrated to be present in homogenous preparations of calf thymus transferase, but only the α and β peptides are present (Protzel and F.J.B., unpublished result). All species react with anti-TdT in microdiffusion tests. The immunoprecipitation procedures provide clean resolution of questions about peptide structure.

Our major objective in these experiments was to analyse a system exhibiting nuclear localisation of transferase. Having found a distinctly different form of transferase peptide in 'non-thymic' cells, we suggest that differentiation in the thymus may lead to peptide chain cleavage producing the 'thymic' form of enzyme. Of even greater speculative interest is the possibility that the high MW form, that form present in the nucleus, may be the form exhibiting important biological activity.

Stopped visual motion

WHILE undertaking another experiment, we discovered a surprising and dramatic visual phenomenon. We were observing two gratings of high contrast and different spatial frequency (see Fig. 1 inset) while both gratings were rotating at a rate of 1 revolution per min. Both gratings were easily visible at the viewing distances used. The coarse grating was seen to revolve as expected; however, the fine grating appeared to revolve very slowly. This phenomenon has been shown to over 100 people¹ and all were startled by the observation. The individual reaction was to assert that the two gratings must be rotating at different physical speeds. This disbelief was readily corrected by removing the two gratings from their turntables and replacing each of them in the position of the other. Another entertaining variation of the observation is to observe the fine grating at the distance where it is perceived as a uniform disk; naturally, no movement can be seen at this distance. If one now advances slowly towards the grating it is initially seen as stationary; as one approaches closer it is seen to rotate progressively faster. At a particular distance it seems to rotate faster than the coarse grating. We have quantified these causal observations and show here that the

Fig. 1 Velocity match for gratings of different spatial frequencies—the dotted line is the true physical rate of revolution. The vertical bars are ± 1 s.e. ($n = 5$). The diameter of the disks was 10 cm.

perception of slow rotation movement is related to the spatial frequency and contrast of the pattern which is rotated.

A 1-cycle deg⁻¹ grating was used as reference and it was rotated at 1 revolution per min. A second grating was attached to a variable-speed turntable which could be controlled by the subject. In the first experiment the subject was requested to look fixedly at one or the other turntable alternately. He then adjusted the speed of rotation until the two disks were matched in velocity.

The results are shown in Fig. 1. The horizontal dotted line is the 1 cycle min⁻¹ reference velocity. It is clear that as the spatial frequency (fineness of the grating) is increased the apparent velocity rises, reaching a peak at 4 cycles deg⁻¹. Thereafter, the apparent velocity slows down rapidly.

Further quantitative observations established that the following variables affect the phenomenon. If the control grating is centred on the fovea and a grating of identical spatial frequency is viewed in the periphery of the visual field, the peripheral grating is seen to move much more slowly. In this experiment the subject looked with his fovea at a reference grating of 2 cycles deg⁻¹ with a velocity of 1 rotation per min. With reference to the foveal standard grating the velocity match of a grating of identical spatial frequency at the following eccentricities were: 5°: 1.4 ± 0.2 ; 10°: 2.2 ± 0.2 ; 15°: 3.2 ± 0.2 ; 20°: 3.7 ± 0.3 ; 25°: 5.4 ± 0.2 .

At very low contrasts (near threshold) the perceived speed of rotation also slows down or stops. However, at medium and high contrast no change in the rate of rotation is found as a function of contrast.

The above observations suggest two separate mechanisms for detecting rotation. In the first, the motion is actually seen; in the second, no motion is seen, but if the subject looks for some time he deduces that rotation must be occurring for he remembers that some time before, the grating was, for example, at 12 o'clock and now it is at 3 o'clock, and so on. When he cannot see the real motion, the observer is left with the strange impression that somehow the continuity of the flow of physiological time is lost.

Neurophysiological studies on single neurones of the visual system are now required to establish whether this singular deception of motion is due to an insensitivity of visual neurones to rotary disks containing high spatial frequencies.

READABLE

Trends in NeuroSciences

THE FIRST MAGAZINE FOR NEUROSCIENTISTS

Launched in July 1978, **Trends in NeuroSciences (TINS)** provides a forum for discussion and comment across the many disciplines in the neurosciences. Central to the concept of the magazine are the review articles which, in the first issues, covered such varying topics as schizophrenia, neural control of the ovary, olfaction, infantile autism and brain sexual differentiation.

These are supported by continuing series on specific topics such as the Neuronal Environment, Neurotransmitters and Neuroplasticity. Last but not least are the news items, meeting reports, book reviews, neuroscience calendar, and the regular columns 'Network Notes' and 'Neuroscience Centres of the World'.

Trends in NeuroSciences has been acclaimed by the neuroscience community —

"It is both useful and fun — a highly unusual combination"
"Full of valuable information and of extremely interesting articles"
"Helpful... in gaining a general overview of neuroscience"
"It is indeed a most informative journal"
"... very informative, readable and attractive".

Trends in NeuroSciences is the cohesive voice of neuroscience, promoting discussion and comment between: neurophysiologists, neurochemists, psychologists, psychiatrists, neuropharmacologists, neuroendocrinologists and neurologists.

Trends in NeuroSciences —
personal edition 12 monthly issues

A sociobiologist's new testament?

John Lawton

Behavioural Ecology: An Evolutionary Approach. By J. R. Krebs and N. B. Davies. Pp.494. (Blackwell Scientific: Oxford, 1978.) Paperback £8.50; hardback £18.

LARGE parts of this book are not really about ecology, and at least one chapter is not even about behaviour. Indeed, it might be more accurately (but still incorrectly) have been sub-titled *A Sociobiologist's New Testament*. The introduction says that it "takes modern population biology as its foundation and explores areas in which ethology and population biology overlap. Evolutionary thinking permeates the whole book", a statement of intent, which very clearly echoes E. O. Wilson's "Attempt to codify sociobiology into a branch of evolutionary biology and particularly modern population biology" (*Sociobiology. The New Synthesis* p4; Harvard University Press, 1975).

The text is divided into three sections, with an introduction (chapter 1) written by the editors. This chapter is an overview of ecology, natural selection and social behaviour, focusing particularly on the questions those who write later in the book will try to answer, and the tools with which they will answer them: optimality models, ecological stable strategies, and broad comparisons across species, together with brief summaries of the necessary genetics, the problems of altruism, inclusive fitness and group selection.

The first section contains four chapters, grouped round the theme "How animals harvest food, and how they avoid being eaten". Krebs discusses optimal foraging; Bertram the whys and wherefores of living in groups; Heinrich the economics of insect sociality, and Harvey and Greenwood anti-predator defence strategies, all topics that can properly be called behavioural ecology with the balance of the emphasis shifted towards one or the other of these words.

Part 2 (Sex, Mating and Signals) has five chapters with rather less unity. Maynard Smith under the heading "The Ecology of Sex" tackles the fascinating question of why organisms bother to reproduce sexually, with a brief look at parental care: excellent, no nonsense stuff which deserves (and has) a recent book to itself, but not

really ecology or even behaviour. Halliday in chapter 7 considers sexual selection and mate choice, followed by Parker who, as a colleague recently remarked, has the problem of mate choice "off pat" (for the uninitiated he studies dung flies). These two chapters complement one another well, as does Emlen's discussion of the evolution of cooperative breeding in birds. With less pleasing logic the section closes with a look at animal signals (by Dawkins and Krebs) under the pretext that the classical ethological work on signals was based on studies of sexual displays. The flavour of this whole section is very strongly behavioural, with only Emlen's chapter having much content that is strictly ecological, although this is intended as a signal of my own chauvinism rather than as a criticism.

The final section of the book tackles the problem of how an individual should deploy its behavioural options in space and time. Davies writes about territorial behaviour, and Partridge about habitat selection, both central themes in behavioural ecology. McCleery then carries us very firmly to the edges of modern behavioural theory with a chapter on how animals should make decisions about whether to mate, fight or feed, rather than what they should do within any one of these behavioural repertoires—the main concern of the rest of the book. Finally, Horn looks at life-history strategies, swinging us back to the mainstream of ecology with a chapter that contains some pleasing pot-shots at over-elaborate theory, some brilliantly simple insights, and almost no behaviour.

It ought, by now, to be clear that I found the book as a whole something of a mixed bag—an ecological, behavioural and sociobiological lucky dip—although like most lucky dips it is full of surprises and great fun to try. My feeling is that the editors have included just a bit too much. On the one hand there is material (for example, optimal foraging) that is certainly not sociobiology, and on the other, things that have precious little to do with mainstream ecology, or even behaviour. Perhaps we simply need a new pigeon-hole: but what should we label it?

With so many themes running

through it, it is difficult to provide one simple overview. Let me therefore close by developing three. As a teaching tool it will undoubtedly be valuable for students of all ages beyond first or second year undergraduate level. It is remarkably up to date, and covers well a host of complex ideas using hardly any mathematics (Parker's chapter is an exception in that he develops some formal models fairly extensively). Above all else it tends to avoid the glib phrase which hides a pit of uncertainty. Where there are problems it says so; and where there are exciting new roads to explore, it clearly signposts the way.

The book was presumably planned to complement R. M. May's *Theoretical Ecology*, which has the same publisher and format (for review see *Nature* 264, 138; 1976). Indeed, with the exception of Wilson's chapter in the latter, and Horn's chapter in the present book, there is almost no niche overlap between them. In combination they cover a massive area and might well be used together for advanced classes.

I suppose the real proof of a testament, old or new, is whether it will convert the hardened cynic: those who will argue that the whole edifice is but a harmless tautology. Throughout, behaviour is interpreted in terms of its survival value, what is in some sense 'optimal' or 'best'. And what is best? Obviously that which survives. The danger of slipping into this way of thinking is very real, because the sufficiently ingenious investigator can almost always dream up a convenient post-hoc Darwinian explanation for awkward observations, and without further testing, sit back contentedly having solved everything and nothing. Indeed there is more than a hint of this problem in several places throughout the book. For example, several authors make some very sweeping assumptions about the manner in which food 'must' be distributed in space and/or time, without actually measuring it, even though their original intention was to understand patterns of behaviour in relation to food supply. Even when ideas can be tested, they are difficult to refute because failure of the hypothesis can rather easily be attributed to "the rather artificial task with which [the animals] were faced" (p55); although

the artificiality of the situation can be conveniently ignored when the experiment 'fits' (for example, p44). However, and to be fair, a great deal of the experimentation and hypothesis testing is eminently reasonable. Indeed the editors have obviously anticipated most of the criticisms, and have been at pains both to draw attention to them, and avoid their worst excesses. What the book as a whole very clearly demonstrates is that if we accept the

central tenets of neo-Darwinism, and then use these tenets to generate interesting hypotheses and make predictions that can be independently tested, a great deal of behavioural ecology starts to make sense. At least, and on balance, it convinced this particular cynic. □

John Lawton is a Senior Lecturer in Ecology in the Department of Biology at the University of York, UK.

Unity in the sensory systems

The Unity of the Senses: Interrelations among the Modalities. By L. E. Marks. (Academic: New York, San Francisco and London, 1978.) \$17.50; £11.35.

IN 1974 Dr Marks published a book on psychophysics and followed this a year later with an article on synaesthesia. In the present book he combines these two interests with his interest in nineteenth-century poetry. The theme which serves as a link, provides a title for the book.

The first three quarters of the book leads to the conclusion that the sensory systems are more than discrete information channels, they demonstrate some unity. The evidence upon which this conclusion is based is grouped under four headings each of which is, for Dr Marks, a doctrine. To quote his rather ill-chosen words "Each chapter therefore amalgamates one of the doctrines with the evidence that highlights it."

The first of these four chapters which form the core of the book, is concerned with the way in which the various senses cooperate in the perception of size, form, space, time, motion and number. The second explores the possibility that there are supra-sensory qualities—brightness is an example—shared by the sensory systems. The third doctrine states that different senses have similar psychophysical properties. Generations of students reared on a diet of Fechner, Weber and Stevens would not disagree. The doctrine of neural correspondence completes the quartet. It states that there is a neural analogue for each of the preceding psychological doctrines. In fact the chapter is mainly concerned with the way in which the sensory systems code intensity, but it does include some interesting philosophical icing.

These four chapters lead to the final chapter of the first part of the book, which turns out to be a very brief discussion of the possibility that the similarities between the senses are best

understood if each sensory system is considered as a modality of a general primitive sense from which it has evolved. The remaining part of the book provides many examples of how the unity of the senses reveals itself in the language of the poet.

I found this a disappointing book. First, it is badly written. Nobody should use language as carelessly as does Dr Marks. Even his definition of synaesthesia, a central concept, lacks precision. Second, the book is shaped by the author's psychophysical interest and expertise. The senses are analy-

zers, but (surprise!) they demonstrate some degree of unity. Perhaps this can be explained by their evolution from a more primitive sense. But should these signs of unity cause surprise? True the senses are analysers but because of their input into the reticular formation they are also very much involved with the integrative mechanisms of the body. The greater the degree of specialisation of the analysers the more complex and the more important are the integrative mechanisms.

Coghill and the Herricks with their partial patterns, which are concerned primarily with the analysis of experience and action, and total patterns, which are synthetic and which maintain the integrity of the living body, would have approached the problem differently. Perhaps the influence of their sort of biology would have provided a more useful foundation than the influences which led to the psychologist's psychophysics.

J. R. Symons

J. R. Symons is Professor of Psychology at the University of Aberdeen, UK.

Chemical kinetics

Principles of Chemical Kinetics. By G. G. Hammes. Pp. 268. (Academic: New York, San Francisco and London, 1978.) \$19.50; £21.50.

THIS book, which is intended for graduate and senior undergraduate students, provides a general introduction to chemical kinetics covering reactions in the gas phase, reactions in solution and enzyme kinetics. In dealing with such a wide spread of topics in a relatively small book the author has had to be selective in the examples chosen, but he has generally been careful to avoid oversimplification. In cases where the principles are illustrated by quite simple examples the nature of possible complicating factors is also pointed out and references are provided to more detailed treatments. The short but well-chosen reference lists at the end of each chapter provide valuable sources of supplementary material and allow the reader to pursue individual topics in greater depth.

The development of the material in this book has been well planned with the reader being led naturally from one topic to another. The balance between the theoretical and empirical aspects of the subject is also carefully maintained with the author taking pains to point out the difference between the

theoretically achievable and the practically possible. Emphasis is given to relatively recent developments in experimental technique and to areas of particularly active current research interest in a way that successfully captures some of the author's own enthusiasm for the subject. Not surprising, in view of the author's own fields of interest, the sections on fast reactions in liquids and transient phase enzyme kinetics are especially valuable in this respect. A particularly useful feature of this book is the carefully thought-out problems at the end of each chapter that provide a challenging test of the reader's understanding of the material presented.

It is perhaps a measure of success of this book in stimulating the reader's interest, rather than a criticism, that there are several sections that I felt could have been given more space, although not at the expense of any of the other material. From my own prejudiced viewpoint I would have liked to have seen more space devoted to enzyme kinetics because of the successful way in which the author relates this subject to its background in chemical kinetics rather than treating it as a topic in isolation. I would have no hesitation in recommending this book most highly as a lucid and stimulating introduction to its subject.

K. F. Tipton

K. F. Tipton is Professor of Biochemistry at Trinity College, Dublin.

Sociobiology: Sense or Nonsense?

by Michael Ruse

xiii + 231 pp.

Paper Dfl. 20,- / US \$ 9.95

Cloth Dfl. 60,- / US \$ 29.00

ISBN 90-277-0940-8

ISBN 90-277-0943-2

Sociobiology is one of the more contentious issues to have ruffled scientists this decade. Slanging matches have been conducted between leading biologists, pandemonium has broken out at conferences, the subject has been branded as a racist science, and the sociobiologists have been likened to reactionary political thinkers.

To evaluate this emotive topic, Michael Ruse, a philosopher of science, scientifically and philosophically analyses these controversies 'to see what case can be made for sociobiology and what case can be made against it'. He impartially discusses subjects such as animal and human altruism, racism, sexism, homosexuality, capitalism, falsifiability, and coherence. The current status and the future of sociobiology is assessed and the possible effects on the social sciences are considered.

The leading exponent of sociobiology, Edward Wilson, says that Ruse's book is the best written to date and is done so with unusual clarity. Indeed, the layman will find the book eminently readable and enlightening.

Megalithic Remains in Britain and Brittany

A. Thom and A. S. Thom

This book continues and extends *Megalithic Sites in Britain* and *Megalithic Lunar Observatories*. All the sites are analysed geometrically and the units of measurements used by the builders are deduced and shown to be universal. Particular attention is given to the astronomical significance of the larger sites, and the background is set out so that the non-specialist reader can follow the argument. Illustrated £8.95

Collected Papers of G. H. Hardy

Including Joint Papers with
J. E. Littlewood and others

Volume VII: Integral Equations, Integral
Transforms, and Miscellaneous Papers

Edited by I. W. Busbridge and R. A. Rankin

This is the final volume in a series the object of which has been to render more accessible the papers of the great mathematician, which in their original form appeared in many journals over a period of almost sixty years. This last volume covers Fourier transforms, integral equations, miscellaneous papers including papers on set theory, differential equations, and the Hardy-Weinberg law, questions from the *Educational Times*, and obituary notices and reviews by Hardy. £30

Psychopharmacology of Affective Disorders

Edited by E. S. Paykel and A. Coppen

This book discusses the diverse disciplines, experimental and clinical, involved in the study of the psychopharmacology of affective disorders. Advances in knowledge of underlying brain mechanisms and in the development of pharmacological treatments are examined and re-evaluated. It will interest post-graduates and undergraduates in medicine, psychiatry, pharmacology, and psychology practising psychiatrists; and others interested in psychiatric treatment. £12.50 *Oxford Medical Publications*

The Nature of Human Aggression

Ashley Montagu

In one of the most important books of his career Ashley Montagu debunks the currently fashionable theory that man is a born killer. He takes issue with the innate aggressionists — Lorenz, Ardrey, Tinbergen, Morris, and others — and sets forth the scientific evidence for an alternative view. First published in 1976, the book is now available in Oxford Paperbacks. £2.50

(Minimum quantity 0.5kg @ £280)

Escherichia coli B

A source of ribosomes, DNA polymerase I, RNA polymerase, DNA ligase and exonuclease III.
(Minimum quantity 2kg @ £190)

Clostridium pasteurianum WS

Grown at 30°C, a source of ferredoxin.
(Minimum quantity 0.5kg @ £168)

All these products can be supplied to overseas customers.
69 other types of cell paste are also available.

The listed products are offered at the quoted sterling prices, which remain firm until 31 March 1979, subject to availability. Prices include packing in dry ice, and delivery on UK orders, which are subject to VAT at ruling rates. Overseas orders are subject to transport charges at cost. For listed items please send your official order to the:

Mycotoxins

Toxicology, Biochemistry and Pathology of Mycotoxins. Edited by K. Uraguchi and M. Yamazaki. Pp. 288. (Halsted/Wiley: New York and London; Kodansha: Tokyo, 1978.) £19.50.

"THE concept of mycotoxins is not yet widely appreciated" is a key statement in the preface to this book. To most laymen the notion that common moulds may produce potent animal toxins may be novel, but many industrial organisations involved in the production of human and animal foodstuffs are becoming well aware of mycotoxins. As is to be expected with a new branch of science which just happens to embrace one of the most carcinogenic substances, opinions vary from those who would attribute to mycotoxins several human and animal syndromes of unknown aetiology, to those who may have good commercial reasons to claim that there is little evidence that these substances have ever done any harm, particularly to humans.

The literature on the mycology, chemistry, biochemistry and pathology of mycotoxins has, in the past fifteen years or so, been evidence of one of the fastest growing facets of biological science. The first comprehensive review was included in the 1971-72 Academic Press series *The Microbial Toxins*. In the past year Marcel Dekker have published their three-volume *Encyclopedic Handbook* which, although it took several years to produce, is perhaps the most comprehensive current text. The present book is a useful and interesting addition to the review literature. It is unique in that it is written entirely by eight Japanese scientists, all of whom have published in the areas they review. It is natural, therefore, that there should be a thread of national emphasis through the book, in which the subject is treated mainly in the context of foodstuffs.

Western literature has tended to ascribe the origin of the recent wave of mycotoxin research to the 'Turkey X' syndrome in England during 1960. It is therefore salutary that the introduction to this book should emphasise the precedence of Japanese research into an epidemic of human acute cardiac beriberi in Japan between the two world wars. These studies led to the isolation of the yellowed rice toxins in the 1940s, though too late for direct verification of their involvement in the aetiology of cardiac beriberi—the epidemic by then having passed away, apparently, for good.

A notable feature of this book is the high standard of readability of the text. Several 1976 references are included, implying that the book can

claim to number among its 1,000 references most of the relevant studies available for review. It would be possible to instance a number of minor errors and omissions in the text but since mycotoxicology is expanding so quickly there is much to commend fairly rapid publication of a review-type book before it becomes too outdated.

The first chapter lists important mycotoxin-producing fungi and their significance concerning foodstuffs. The second chapter on the chemistry of mycotoxins is subdivided according to biosynthetic features, a treatment reminiscent of W. B. Turner's important 1971 book on fungal metabolites. The next three chapters are devoted to toxicology, the main topic of the book. There are sections on general and comparative toxicology. The fate, metabolism and mutagenicity of mycotoxins are discussed and cellular alterations, histopathology and carcinogenicity are liberally illustrated. As the chronic carcinogenic properties

of certain mycotoxins, notably aflatoxin, are of particular relevance to humans, the book concludes with a short chapter on traditional Japanese fermented foods, home-grown rice and imported peanuts and peanut products. Traditional foods are given a clean bill of health as the selection over many centuries of *Aspergillus* 'koji-moulds' for the preparation of miso, sake and soy sauce seems not to have included any capacity for aflatoxin biosynthesis. Further, the absence of aflatoxin from mouldy rice, otherwise contaminated with ochratoxin A and the aflatoxin precursor, sterigmatocystin, suggests that aflatoxin producing moulds are not indigenous to the relatively high latitudes in which Japan is situated.

This book is to be commended as providing a most useful oriental view of mycotoxicology.

P. G. Mantle

P. G. Mantle is Senior Tutor in Biochemistry at Imperial College, University of London, UK.

Physiology and pathology of the neutrophil

The Neutrophil: Function and Clinical Disorders. By S. J. Klebanoff and R. A. Clark. Pp. 810. (Elsevier/North Holland: Amsterdam, 1978.) \$148; Dfl.333.

IN recent years immunologists have focused their attention on macrophages and lymphocytes and minimised the importance of the neutrophil as a component of the cell-mediated defence system. This excellent book should help to redress the balance by stimulating interest in this fascinating cell by supplying a comprehensive account of contemporary knowledge of its physiology and pathology and a thorough citation of the literature.

In these days of specialisation a work as comprehensive as this, encompassing over 800 pages and possibly five times as many references, is generally tackled by a team of expert contributors. One of the strengths of this book is that the authors do not have vested interests in most of the contents and as a result the facts are presented in an unbiased manner without any attempt to influence readers' interpretation of the data. This has resulted in a highly informative exposition of current concepts that are expressed clearly and concisely. The mass of information that has been assembled is more suitable as a source

of reference than as an easily readable introduction to this cell.

A wide range of topics of cell biology and pathology have been systematically covered, including both normal and disordered structure, movement, phagocytosis, degranulation and antimicrobial systems of the cell as an entity, and its interaction as a component of the inflammatory process as a whole. The discussion of clinical disorders of neutrophil function covers the well known primary cellular defects such as Chronic Granulomatous Disease, myeloperoxidase deficiency and the Chediak-Higashi syndrome in addition to those abnormalities of function which occur as a consequence of abnormal humoral immunity or in association with systemic disease. There is little direct description of laboratory methodology, although this would be readily available from the literature references; and the rapidly expanding subject of leukapheresis and granulocyte transfusion is hardly touched upon.

The book is well produced, with numerous figures and diagrams. The index is extensive and comprehensive, as befits a reference volume. It will be of use to clinicians in the fields of infectious diseases, immunology, haematology and rheumatology, and an essential addition to the library of experimental biologists, particularly those with an interest in host defence in general and in the neutrophil in particular.

Anthony Segal is at the MRC Clinical Research Centre, Harrow, UK.

Soil constituents

The Chemistry of Soil Constituents. Edited by D. J. Greenland and M. H. B. Hayes. Pp 469. (Wiley: London and Chichester, UK, 1978.) £26.

THIS enterprise is most welcome, as apart from the two encyclopaedic volumes (*Soil Components*, Springer: Berlin, 1975) edited by J. E. Gieseking, no advanced textbook of soil chemistry has been published for many years. The editors consider their subject falls naturally into two parts, the present volume *The Chemistry of Soil Constituents* covering static aspects, and a volume to be published shortly *The Chemistry of Soil Processes* covering dynamic aspects.

The introductory chapter (28 pages) by the editors places the topics of later chapters in the context of soil science as a whole. Chapter 2 (150 pages) entitled 'The Structures and Chemistry of Soil Clay Minerals' by the Rothamsted team of G. Brown, A. C. D. Newman, J. H. Rayner and A. H. Weir is a book in itself. Although clear accounts of the classical aluminosilicate clays already exist, for example, by Grim, this chapter treats the inorganic oxides and fibrous magnesium silicates more fully. Recent developments in two directions are particularly well described. Many soil clays consist of interstratified minerals in which different types of unit—kaolinite, smectite, and so on—alternate in a regular or irregular manner, and the account of the unravelling of these structures is very valuable. Soils developed from weathered volcanic ash commonly have such unusual features as a bulk density less than 0.85 g cm^{-3} . They contain the thread-like mineral imogolite and amorphous allophane; and the confused literature on these substances has been clarified. The excellent electron micrographs are a feature of this chapter. Much trouble has been taken to show complicated structures in two-dimensional diagrams, but this remains a problem, and I would like to have seen some stereopairs.

Chapter 3 (122 pages) entitled 'The Chemistry of Soil Organic Colloids' by M. H. B. Hayes and R. S. Swift deals with the chemical and physical properties of humified substances—not the materials from which they are derived, so lignin and polyphenols, for example, receive little mention. Those who have already decided that humus chemistry is a complex topic best left to its specialist devotees are unlikely to

change their opinion on reading this chapter. The authors rightly emphasise experimental methods of fractionating the humus moieties, and discuss how reliably they have been identified. The size, shape and weight of humus polymers are clearly described. Humic substances are distinguished in this account from "compounds belonging to recognisable classes, such as polysaccharides, polypeptides and altered lignins". The polysaccharides are thoroughly treated in a separate section, but the organic forms of nitrogen, sulphur and phosphorus receive no attention.

The rest of the book concentrates on surface phenomena. C. J. B. Mott and D. J. Greenland (chapter 4, 29 pages) describe the structure of the mineral surfaces and the determination of their area. G. W. Arnold (chapter 5, 44 pages) deals with surface charges and V. C. Farmer (chapter 6, 38 pages) with the structure of water on the surfaces. Together these chapters contain by far the most coherent account of soil surfaces yet assembled. Arnold's discussion of the point of

zero charge in soils is particularly illuminating. I wish he had treated the effect of Ca^{++} ions in ordering adjacent clay tactoids more thoroughly. The electrical double layer theory he so well describes does not account for this effect, on which the structure of most soils, and thus agriculture, depends. This latter section of the book cries out for a discussion of the affinity of the various surfaces for cations and anions, and a comprehensive account of cation and ligand exchange. These matters are to be treated in the second volume.

The writing throughout is clear and concise, and there are few serious errors. The index is good and the general standard of production high—so too is the price, though the scientific value per page is well above average. The book is unlikely to be replaced for at least a decade, so I rate it a good though expensive buy for all advanced students of soil chemistry.

P. H. Nye

P. H. Nye is Reader in Soil Science at the University of Oxford, UK.

Introductory oceanography

Introductory Dynamic Oceanography. By S. Pond and G. L. Pickard. Pp. 240. (Pergamon: Oxford, 1978.) Hardback £15; paperback £5.

ALTHOUGH a number of books published recently have given a general introduction to physical oceanography, a need has remained for a textbook providing a sound dynamical treatment, starting from first principles. This gap has been filled by Pond and Pickard's new book, which has evolved from a course of lectures given for a number of years at the University of British Columbia to students drawn from several disciplines. Its origin is reflected in the detailed explanations of many concepts which are frequently taken for granted in textbooks.

The book starts with a description of the properties of sea water and the basic physical laws relating to movements of water in the sea. There follows a clear explanation of the equations of continuity and motion, including a good discussion of the Coriolis effects. The influence of non-linear terms is given a separate chapter, which includes a discussion of the scales of terms in the equations of motion and introduces the role of the Rossby, Ekman and Richardson numbers in this context.

The chapter devoted to frictionless geostrophic flow gives a thorough treatment of the basic dynamics and its practical application to oceanographic data. The longest chapter in the book is that on currents with friction, which starts with the classical Ekman spiral theory and leads on to solutions applicable to the large scale wind-driven circulation of the oceans. The treatment of the boundary layer approach given in the last part of the chapter is more advanced than the rest but is well done.

A feature of particular interest is the inclusion of a chapter on numerical models. Without going into computational details, it gives a good account of the principles of modelling the ocean circulation and the treatment of boundary conditions, followed by a description and critical discussion of several individual models. The chapters on waves and tides are less detailed than the rest of the book and are largely qualitative. There are, however, other textbooks which deal with these topics.

The authors have succeeded in producing a textbook which will not only give the reader a basic understanding of physical oceanography but also bring him to the stage where he can appreciate advances being made at the frontiers of the subject.

K. F. Bowden

K. F. Bowden is Professor of Oceanography at the University of Liverpool, UK.

Baylor College of Medicine

TEXAS MEDICAL CENTER • HOUSTON, TEXAS 77030

STABLE ISOTOPE FACILITY DIRECTOR, CHILDREN'S NUTRITION LABORATORY

The United States Department of Agriculture has established a Children's Nutrition Laboratory under the Human Nutrition Center, Science and Education Administration. This laboratory is located within and administered under a cooperative agreement with Baylor College of Medicine and Texas Children's Hospital in Houston, Texas. The mission of the laboratory is the determination of nutrient requirements in infants and children during an age range which spans from conception to the adolescent. The emphasis is on normal nutrient requirements as a standard for the many applied programs in human nutrition of the Federal Government.

Because of the mandate to investigate nutritional requirements in normal children, it is determined to be essential that a Stable Isotope Facility be established as part of this national laboratory for childhood nutrition research. The Stable Isotope Facility will participate in intramural and extramural research projects which are designed to utilize the facility for stable isotope nutrient synthesis, nutrient isolation, and atomic mass ratio measurement and interpretation.

A Director of the Stable Isotope Facility is being sought to provide leadership in research development and operation of this national facility. This scientist should be an experienced biologist, physiological chemist or nutritionist who has demonstrated academic capacity and administrative experience in metabolic research utilizing mass spectroscopy. The Director of the division ideally should be a physician, however, this is an optional requirement.

Those interested in evaluating this opportunity for scientific leadership should correspond with John S. Woods, Personnel Director, Baylor College of Medicine.

An Equal Opportunity Employer

9983(A)

SENIOR BIOCHEMIST/ STAFF PHARMACIST

This new post will be in our Area Clinical Pharmacology Department. The successful applicant will work under the medical direction of the Area Clinical Pharmacologist and will develop and supervise assay methods for the investigation of drug based problems, phase one drug studies, clinical trials and the routine estimation of selected compounds.

Applicants should be graduates in Biochemistry, Chemistry, or Pharmacy, or their equivalent. They will have had at least four years' relevant post-graduate experience and be familiar with G.L.C. or H.P.L.C. techniques. The post involves laboratory management and supervision of the Biochemist, Research Pharmacist and Technician in post, and of a second Pharmacist, second Technician and part-time nurse to be recruited. Research and co-operation with the University Department of Clinical Pharmacology and Therapeutics will be encouraged.

Salary for this post is on the scale £5,451 per annum to £6,837 per annum. It is likely that new entrants to the Health Service will start on the minimum of the scale.

Application forms and job descriptions are available from the Personnel Department, 10 University Road, Leicester. Tel. Leicester 28464.

Closing date for completed applications is March 21. 9957(A)

UNIVERSITY OF THE WEST INDIES—JAMAICA

Applications are invited for three posts of

**SENIOR LECTURER/
LECTURER/
ASSISTANT LECTURER**

in the

DEPARTMENT OF PHYSIOLOGY

Appointees will be expected to participate in the development of the teaching and research programme of the Department. Particular emphasis will be placed on applicant's experience in the fields of neurophysiology, neuromuscular physiology, endocrinology and cardiovascular physiology. The Physiology Department teaches medical students preparing for the MBBS Stage 1 Part 1 Examination of the medical course, B.Sc. (Special) Physiology and Postgraduate Residents in the Faculty of Medicine.

Salary scales: non-medical, Senior Lecturer, J\$12,066 to J\$15,897 p.a.; Lecturer, J\$8,913 to J\$13,917 p.a.; Assistant Lecturer, J\$7,236 to J\$7,926 p.a.; medical, Senior Lecturer, J\$15,339 to J\$19,326 p.a.; Lecturer, J\$11,262 to J\$15,015 p.a.; Assistant Lecturer, J\$9,102 to J\$9,936 p.a. (£1 sterling = J\$3.42.) F.S.S.U. Study and Travel Grant. Unfurnished accommodation will be let by the University at a rental of 10% of salary or a housing allowance of 20% of salary will be paid. Family passages.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees should be sent as soon as possible direct to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica.

Applicants resident in the U.K. should also send one copy to the Inter-University Council, 90-91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 9915(A)

UNIVERSITY OF OTAGO Dunedin, New Zealand

**VISITING
ASSISTANT LECTURER
IN CHEMISTRY**

Applications are invited for the position of Visiting Assistant Lecturer in the Department of Chemistry.

Applicants should hold a Ph.D. degree or its equivalent and have had some postdoctoral teaching or research experience in inorganic chemistry. The position would suit an applicant who wishes to take sabbatical leave, as ample opportunity will be given for research.

The position is for one year from August 1, 1979, although consideration would be given to an earlier starting date, or for tenure for less than one year.

Salary scale: NZ\$8,682 to NZ\$10,659 per annum.

Further particulars are available from the Association of Commonwealth Universities (Acpu), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close on April 30, 1979. 9931(A)

POSITION AVAILABLE THE INTERNATIONAL POTATO CENTER

APARTADO 5969, LIMA, PERU

Announces a postdoctoral position in agronomy. Research duties will be concerned with optimizing potato production in tropical locations.

A candidate should have a Ph.D. degree in agronomy and be familiar with fertilizer, water and crop management strategies appropriate to optimizing crop yields. Field experience with potato production while desirable is not essential.

The position is for a three-year term and following an initial orientation in Peru, the successful candidate will be stationed in south-east Asia. The position offers an excellent opportunity to become familiar with international agriculture in developing countries in the tropics.

Please contact Dr S. Sadik, Head, Department of Plant Physiology, for application forms (air mail). 9990(A)

UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF BIOCHEMISTRY POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited from biochemists, molecular biologists or microbial geneticists to join a group investigating DNA repair and genetic recombination in *Escherichia coli*. The project is supported by the Medical Research Council until March 31, 1981. The work will involve a combination of biochemical and genetic techniques, and previous experience in nucleic acid biochemistry, molecular genetics, enzyme purification or DNA cloning would be advantageous.

Commencing salary will be within the scale £3,883 to £6,535 (under review) with full superannuation provision.

Applicants should send a curriculum vitae and the names of two referees to Dr P. T. Emmerson, Department of Biochemistry, University of Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU. 9948(A)

**THE AUSTRALIAN
NATIONAL UNIVERSITY
RESEARCH SCHOOL OF
BIOLOGICAL SCIENCES
DEPARTMENT OF
DEVELOPMENTAL BIOLOGY
POSTDOCTORAL FELLOWS
(two positions)**

The appointees will work with Professor B. E. S. Gunning on a programme of research on ultra-structural aspects of morphogenesis in plants, with emphasis on the roles of microtubules. Applicants should have experience of electron microscopy.

POSTDOCTORAL FELLOW

The appointee will work on problems of compartmental analysis in plant cells. Applicants should have experience in this and related fields of short distance transport in plants.

Appointments will be for two years. CLOSING DATE APRIL 15, 1979.

Salary on appointment will be in accordance with qualifications and experience, a fixed point within the range \$A15,786 to \$A20,606 per annum. Current exchange rates are \$A1 56p US\$1.13.

Reasonable appointment expenses are paid.

Superannuation benefits are available for applicants who are eligible to contribute. Assistance with finding accommodation is provided for an appointee from outside Canberra.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain further particulars from the Association of Commonwealth Universities (Acpts), 36 Gordon Square, London WC1H 0PF. 9980(A)

**UNIVERSITY OF GLASGOW
DEPARTMENT OF ASTRONOMY**

Applications are invited for a two year (S.R.C.)

**POSTDOCTORAL RESEARCH
ASSISTANTSHIP**

to collaborate with Dr J. C. Brown on developing the theory of interaction of energetic electrons with the solar atmosphere. The research will be oriented toward diagnosing hard X-ray and optical emissions from solar flares observed from NASA's SMM satellite. A background in theoretical physics/astrophysics would be highly desirable, and specific experience in plasma astrophysics or radiation theory/diagnostics advantageous.

Starting date will be between July 1 and December 1, 1979 and starting salary will be toward the lower end of the range £3,883 to £4,882 (under review) + U.S.S. Further details obtainable from Dr J. C. Brown, Department of Astronomy, University of Glasgow, G12 8QQ, Tel. 041-339-8855, Ext. 7183, to whom applications should be sent with curriculum vitae and names of at least 2 referees by May 1, 9979(P)

**THE UNIVERSITY OF
ALBERTA
FACULTY OF AGRICULTURE
AND FORESTRY
Academic Position
ASSISTANT PROFESSOR**

First degree in Veterinary Medicine and Ph.D. in Animal Science with broad interest and experience in Animal (Swine) Breeding and Genetics. Duties will include teaching at introductory and senior levels plus research and extension.

Appointment July 1, 1979 is subject to availability of funds.

Normal starting salary \$19,320 per annum (second step of Assistant Professor range of \$18,530 to \$24,059).

The University of Alberta is an equal opportunity employer.

Forward applications, including curriculum vitae, transcripts and names of three referees, by June 1, 1979 to:

Chairman
Department of Animal Science
Faculty of Agriculture and Forestry
The University of Alberta
Edmonton, Alberta
T6G 2E3. 9968(A)

**CARDIOTHORACIC
INSTITUTE
DEPARTMENT OF
MEDICINE
London University**

Medical Laboratory Scientific Officer required. Experience in immunology desirable. Work will mainly involve the laboratory investigations of immunological responses in patients with lung cancer. Further information and applications, giving details of age and experience to:

Mr R. A. Perkins, Secretary,
Cardiothoracic Institute, Fulham Road,
Brompton, London SW3 6HP, by
May 1, 1979 and quoting Ref. 01/79.
9967(A)

**UNIVERSITY OF
BIRMINGHAM
DEPARTMENT OF
CANCER STUDIES**

Applications are invited for a
LECTURESHP
(non-medical)

In the Department of Cancer Studies.

Candidates should have a higher degree and an established record of research in a field relevant to the study of the aetiology of cancer. The successful applicant will be expected to contribute to teaching programmes for both medical and science undergraduates and to play a role in supervising postgraduate students.

Salary will be in the range £3,883 to £7,754 plus superannuation.

Applications giving the names of three referees should be sent by March 30, 1979, to the Assistant Registrar, Medical School, Birmingham B15 2TJ. Further particulars may be obtained from Professor D. G. Harnden, the Department of Cancer Studies at the Medical School. 9926(A)

**THE UNIVERSITY
OF SYDNEY
PROFESSIONAL OFFICER,
RADIOCARBON DATING**

Applications are invited for a permanent position as Professional Officer in charge of an established radiocarbon laboratory. Appointee will be expected to maintain the consulting work of the laboratory and generate suitable research projects in radiocarbon dating.

Applicants should have a Ph.D. or equivalent research experience. Preference to someone with experience in natural radiocarbon assay using liquid-scintillation counting.

Salary within range for Professional Officer Grade II: \$A15,674 to \$A16,684 per annum. Appointment will commence as soon as possible.

Applications, with curriculum vitae, publications and names of up to three referees to the Registrar, University of Sydney, N.S.W. 2006, Australia, by April 2, 1979. Further details from Associate Professor R. B. Temple, School of Chemistry, in the University. 10010(A)

**IMPERIAL COLLEGE OF
SCIENCE AND TECHNOLOGY
LONDON
LECTURESHP
IN BIOCHEMISTRY**

A vacancy exists for a Lectureship in Biochemistry in the general area of Applied Microbial Biochemistry. Applications from those with interests in the expression of eukaryotic genes in *E. coli*.

For the potential production of medically or industrially useful proteins will be especially welcomed. The Department is fully equipped for the most modern techniques relevant to these interests.

Salary will be within the range £3,883 to £7,754 (under review), plus £450 London Allowance and is subject to U.S.S.

Applications, which should include a curriculum vitae, the names of three referees and a statement of future research plans, should be sent to Professor B. S. Hartley, F.R.S., Department of Biochemistry, Imperial College of Science and Technology, London SW7 2AZ. 10009(A)

**UNIVERSITY OF ABERDEEN
UNIVERSITY OFFICE, REGENT WALK
ABERDEEN AB9 1FX
Tel: 0224-40241**

**DEPARTMENT OF BIO-MEDICAL PHYSICS &
BIO-ENGINEERING**

Research Assistant

Applications are invited for this post in a small group working on an evaluation of properties of short-term cultures of human tumour biopsy specimens with particular reference to their chemosensitivity. Applicants should have a degree in one of the biological sciences. Experience in either tissue culture or cancer research would be advantageous.

The appointment, funded by Cancer Research Campaign, is tenable until 31 October 1979, to commence as soon as possible. Extension for a further year is likely, subject to satisfactory progress.

Salary £3,883 to £4,382 per annum, on Range 1A Research and Analogous Staff Scale, with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by March 30, 1979.

DEPARTMENT OF CHEMISTRY

Research Assistant

Applications are invited for the above post financed by the UK Atomic Energy Authority, under the supervision of Dr G. G. Cameron and concerned with methods of decomposing plastic and other polymeric items. The post is tenable until December 31, 1980 from a date to be arranged as soon as possible. Applicants should hold a university degree or equivalent, preferably at honours level in chemistry.

Salary within Range 1B Scale for Research and Analogous Staff, £3,384 to £4,382 per annum. Candidates interested in a part-time appointment will be considered.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by March 30, 1979.

DEPARTMENT OF GEOLOGY AND MINERALOGY

Postdoctoral Research Fellowship

Applications are invited from suitably qualified organic geochemists or clay mineralogists to work with Dr M. J. Fearson on the correlation of organic matter and clay mineral diagenesis in sediments from the North Sea Basin. The project involves the study of kerogen maturation and hydro-carbon generation during burial in relation to clay mineral transformations as a response to temperature increase and ion concentration in interstitial water.

The post is tenable for three years and is supported by the Natural Environment Research Council.

Salary £4,382 to £4,882 per annum on Research and Analogous Staff Range 1A Scale, with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by March 30, 1979.

DEPARTMENT OF BIOCHEMISTRY

**Postdoctoral Research Fellowship/
Assistantship**

Applications are invited for Postdoctoral Research Fellowship to determine the amino acid sequences of pyruvate kinase; pre-doctoral applicants with suitable interests and experience will be considered. The project is a collaborative one with the protein crystallography group at the University of Bristol, and will lead to a detailed description of the molecular structure of pyruvate kinase. The successful applicant will work in collaboration with a pre-doctoral research assistant already in post, with Dr L. A. Fothergill's research group which is currently studying the structures of four other glycolytic enzymes.

The appointment is supported by the SRC and is available for a period of up to three years. Starting date by arrangement. Salary within Range 1A, £3,883 to £4,882 per annum, with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by April 20, 1979. 10001(A)

free university amsterdam

The Faculty of Medicine, laboratory for Physiology invites applications for the position of a

(senior) research assistant

Applicants should have experience in experimental cardiovascular physiology. Ph.D. degree in Physiology or H.D. degree is required.

Additional information can be obtained from prof. dr. A.A. Knoop, phone 020 - 548 27 19

Candidates are expected to agree with the christian charter of the Free University. Candidates are requested to submit their applications, including a curriculum vitae and names and addresses of three referees, within one month after this announcement, to the Personnel Department, P.O. Box 7161, 1007 MC Amsterdam, the Netherlands, quoting reference no. 216-379. The Free University is situated at the De Boelelaan 1085, 1081 HV Amsterdam, the Netherlands.

9944(A)

AGRICULTURAL RESEARCH COUNCIL INSTITUTE OF ANIMAL PHYSIOLOGY Babraham, Cambridge CB2 4AT SCIENTIFIC OFFICER

required in the Endocrine Laboratory of the Department of Applied Biology. The research involves biochemical analytical methods, experience with such techniques and an interest in electronics would be an advantage. Applicants should have a pass degree, HNC or equivalent in a relevant biological science. Salary in scale £2,839 to £4,415 per annum, according to qualifications and relevant experience. Non-contributory superannuation scheme. Application form and further details may be obtained from the Secretary of the Institute Quote Ref. D.R.B. 2.

Closing date March 23rd 1979
9977(A)

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF IMMUNOLOGY LECTURESHIP IN RADIOBIOLOGY

Applications are invited for the post of LECTURER (non-medical) in RADIOBIOLOGY. Main teaching responsibilities are in the biological side of an interfaculty M.Sc. Course in Radiobiology and Medical Physics, taking 10-12 graduates per year. In addition there will be administrative responsibility in respect of the Faculty radioisotope counting service, and in advising staff and students on the design of projects involving the use of ionising radiations. Adequate time is available for pursuing its associated research in association with Departments in the Faculty or Hospital, depending on the successful applicant's research interests.

Salary on the scale £3,883 to £7,751 plus superannuation

Applications, giving the names of three referees, should be sent to the Assistant Registrar, The Medical School, Birmingham B15 2TT, by March 30, 1979.

Further particulars may be obtained from Professor J. Hardwicke in the Department of Immunology, The Medical School 9977(A)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF BIOCHEMISTRY RESEARCH ASSISTANT

Applications are invited from graduates in Biochemistry or related subjects to work on a project investigating the turnover of specific proteins in normal and abnormal muscle. The project is funded by the M.R.C. and is under the supervision of Dr R. J. Beynon.

The post will be tenable from April 1, 1979, at an initial salary of £3,384 per annum.

Applications, together with the names of two referees, should be received not later than March 30, 1979, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref. RV/514/N 9920(A)

DEPARTMENT OF GENETICS UNIVERSITY OF NEWCASTLE UPON TYNE RESEARCH ASSOCIATE Proteins of Animal Viruses

Applications are invited for the above post (salary scale £3,888 to £6,555) from candidates holding a Ph.D. degree in any of the following fields: virology, biochemistry, genetics or microbiology. The post is to be funded from a Wellcome Trust grant and is tenable for a two-year period (starting date negotiable).

The research will involve the development and assessment of new analytical methods for sequentially ordering peptides from several virus proteins isolated from different strains and mutants of the parainfluenza virus Newcastle Disease Virus (NDV). Work with NDV requires that the successful candidate should not normally come into contact with live birds.

Previous experience with animal viruses, protein or nucleic acid sequencing and tissue culture an advantage. Familiarity with aseptic technique essential.

Written applications including a full curriculum vitae together with the names and addresses of three academic referees should be sent to Dr A. C. R. Samson, Department of Genetics, Ridley Building, The University, Newcastle upon Tyne NE1 7RU.

Closing date for applications: April 6, 1979 9923(A)

QUEEN ELIZABETH COLLEGE Kensington (University of London) POSTDOCTORAL RESEARCH ASSISTANT IN THE DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a post to work on the biosynthesis of collagen in chondrocytes isolated from normal and arthritic cartilage. Particular attention will be paid to post-translational steps in collagen biosynthesis, and a knowledge of collagen chemistry or tissue culture techniques would be an advantage. The appointment will be for up to three years and will commence as soon as possible at starting salary of up to £4,408 per annum (plus London allowance). Further particulars may be obtained from, and applications in the form of a curriculum vitae including the names and addresses of two referees should be sent to, Dr R. G. Price, Biochemistry Department, Queen Elizabeth College, Campden Hill, London W8 7AH. 9963(A)

PORTSMOUTH POLYTECHNIC DEPARTMENT OF BIOLOGICAL SCIENCES 2 RESEARCH ASSISTANTS

required for D.O.E.-supported work on the introduced brown alga *Sargassum muticum*. One post will be concerned with investigating aspects of the alga's physiology and morphogenesis; the other post with monitoring the alga's distribution and evaluating clearance trials.

Applicants should hold, or be about to obtain, a good degree in a biological subject. The post will be for three years, and candidates may be able to register for a higher degree. Candidates should have SCUBA diving ability and a current driving licence.

Salary scale £2,589 to £2,700 per annum.

Application forms and further details from the Staff Officer, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth PO1 2QQ, to whom completed application forms should be returned by March 22, 1979 9940(A)

A.R.C. Animal Breeding Research Organisation BIOCHEMISTRY

A SCIENTIFIC OFFICER required to prepare and carry out radioimmunoassays and assist other experimental work, so with animals, as a member of small team studying the physiology of reproduction and lactation farm animals in the Department Physiological Genetics at Roslin near Edinburgh.

Candidates should have a pass degree, H.N.C. or equivalent biochemistry or biological science and preferably appropriate laboratory experience. Salary on scale £2,839 to £4,415 with start salary depending on qualifications and experience. Non-contributory superannuation.

Further information and application forms obtainable from the Secretary, A.R.C. Animal Breeding Research Organisation, W. Mains Road, Edinburgh EH9 3JF. Closing date March 24, 1979.

9948(A)

THE OPEN UNIVERSITY

Vice-Chancellor

The University is to appoint a Vice-Chancellor to take up office in the spring of 1980 to succeed Lord Par. Persons interested in the appointment are asked to write, in confidence, possible not later than the end of April 1979, to the Chairman of the Committee (Professor B. B. Boycott FRS), c/o The Secretary (JSVC), The Open University, Walton Hall, Milton Keynes, MK7 6AA.

Information about the University and the Office of Vice-Chancellor may be obtained from the Secretary of the University, Walton Hall, Milton Keynes, MK7 6AA. 9962(A)

Careers for Microbiologists..

on the fringe of the Lakes

Glaxo Operations UK Limited is the largest British pharmaceutical company in the UK and is responsible for the UK manufacture of Glaxo pharmaceuticals and their sale in this country. The Ulverston factory, involved in bulk phar-

maceutical production, has one of the country's largest fermentation works and is located in the southern part of the Lake District. The area is renowned for its natural unspoiled beauty and offers a wide range of recreational amenities.

STRAIN SELECTION

A graduate scientist is required to join a large multi-disciplinary Development Unit, which is responsible for finding new strains that will improve our fermentations. The Unit undertakes a wide range of microbial projects, including mutation and breeding studies, selection techniques, screening systems, culture preservation and seed stage development. You will have the opportunity

to contribute in a number of these areas and, therefore, should have a sound knowledge of microbiology or related disciplines, preferably with relevant post-graduate experience. Close collaboration with scientists of other disciplines within the Unit is necessary, and liaison with universities and research institutes will also be involved.

QUALITY ASSURANCE

This is an opportunity in the Microbiological Section to undertake microbiological control and investigational work, initially monitoring production processes and their environments. This will involve you in close liaison with the production function and other disciplines within Quality Assurance. There will be scope later to broaden

your activities into sterility testing and microbiological assay. Career prospects, for example into laboratory management, are good.

You should have a degree in microbiology, preferably with a professional qualification, and have had experience of quality control associated with sterile pharmaceutical production.

For both appointments, salaries will be according to qualifications and experience, together with an opportunity to participate in Glaxo Group profitability. There are the usual benefits associated with a major company, including relocation expenses, where appropriate, to this very pleasant

part of Cumbria.

Please write or telephone for an application form to: Richard Nelson, Personnel Department, Glaxo Operations UK Limited, Ulverston, Cumbria LA12 9DR. Tel: (0229) 52261, ext. 92, quoting ref. U/35.

10011(A)

CARDIOTHORACIC INSTITUTE

(Associated with the National Heart and Chest Hospitals)
University of London

Two appointments in asthma research are vacant. Appointees may be expected to undertake research on animal tissues *in Vitro* and *in Vivo*, as well as participating in clinical research projects. Preferred areas of interest would be smooth muscle pharmacology and second messenger systems.

Applicants should be at graduate or postdoctoral level, pharmacologists or biochemists. The appointment will be as research assistants on the appropriate salary scale for the University. Postdoctoral appointees may be nominated to lectureship; recent graduates would be encouraged to register for a higher degree.

Applications to be made to the Secretary, Cardiothoracic Institute, Fulham Road, London SW3 6HP. 9966(A)

UNIVERSITY OF BRISTOL RESEARCH IN THEORETICAL CHEMISTRY

Applications are invited for a research position at either a postgraduate level (three years) or a postdoctoral level (two years) to carry out research in developing new methods in the field of *ab initio* molecular electronic structure calculations. The research project will be aimed at developing accurate, yet viable, methods for the calculation of wavefunctions and potential energy surfaces of molecules containing chemically interesting atoms with large numbers of electrons. The position is available from October 1979. For further details apply to: Dr G. G. Balint-Kurti, School of Chemistry, Bristol University, Bristol BS8 1TS. 10000(A)

UNIVERSITY OF LEICESTER DEPARTMENT OF PHYSICS RESEARCH ASSOCIATE IN CONDENSED MATTER PHYSICS

Applications are invited for a postdoctoral research associate to undertake a study of liquid semiconducting alloys using photoelectron spectroscopy. The project is part of a wider investigation of the properties of disordered systems being carried out in the Physics Department and supported by the Science Research Council.

The post is tenable initially until September 1981 and the salary is from £3,883 per annum. Applications with a curriculum vitae and the names of two referees should be sent to: Dr C. Norris, Department of Physics, University of Leicester, LE1 7RH. 9999(A)

UNIVERSITY OF NOTTINGHAM

SCHOOL OF AGRICULTURE
TEMPORARY LECTURESHIP
IN SOIL SCIENCE

There will be a vacancy for a Lecturer in Soil Science in the Department of Physiology and Environmental Studies. The appointment will be for two years from September 1, 1979, with a possible extension for the third year, and it will be made in the first three steps of the Lecturer scale.

The main emphasis in the Soil Science Section relates to physical and chemical aspects of soil/plant relationships and it is expected that the person appointed would strengthen these interests: research experience is desirable.

Further particulars and forms of application, returnable not later than March 23, 1979, from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD. Ref. No. 675. 10002(A)

UNIVERSITY OF NEWCASTLE UPON TYNE SCHOOL OF PHYSICS DEPARTMENT OF GEOPHYSICS AND PLANETARY PHYSICS Applications are invited for the post of RESEARCH ASSOCIATE

tenable for one year at a salary of £4,382. The person appointed will work with Dr D. W. Collinson in developing a new type of magnetometer for the measurement of the remanent magnetism of rocks and minerals. Applicants should have a degree in physics or equivalent qualifications, and an interest in instrumentation.

For further particulars write to Dr D. W. Collinson, Department of Geophysics and Planetary Physics, School of Physics, The University, Newcastle upon Tyne NE1 7RU. 9941(A)

UNIVERSITY OF LONDON GOLDSMITHS' COLLEGE New Cross, London SE14 6NW SCHOOL OF SCIENCE AND MATHEMATICS BIOLOGICAL SCIENCES DEPARTMENT

Applications are invited for a half-time

LECTURESHIP IN BOTANY

in the Biological Sciences Department from September 1, 1979 for a period of three years. The person appointed will be expected to provide teaching in the fields of cell biology and evolutionary biology. A good general background in botany would be an advantage.

Salary pro rata on the scale £4,575 by 10 increments to £7,032 per annum inclusive of London Allowance.

Write for further details to the Personnel Officer, to whom applications should be sent by March 30, 1979. 9949(A)

UNIVERSITY OF DUNDEE DEPARTMENT OF BIOLOGICAL SCIENCES Applications are invited for two LECTURESHIPS

in Microbiology in the above Department. No field of interest is excluded but it is hoped that one post will be filled by someone with an interest in microbial/molecular genetics.

The posts are permanent and superannuable under U.S.S. Salary scale (under review) £3,883 to £7,754 with entry at points appropriate to the ages, qualifications and experience of the successful candidates.

Applications (six copies, overseas applicants one copy) quoting Reference F/32/79J and naming three referees should be lodged by March 27, 1979, with The Secretary, The University, Dundee DD1 4HN, from whom further particulars are available. 9936(A)

SCOTTISH HORTICULTURAL RESEARCH INSTITUTE Invergowrie, Dundee DD2 5DA AGRICULTURAL RESEARCH COUNCIL POSTGRADUATE STUDENTSHIP

Applications are invited for a Studentship tenable for three years from October, 1979 in the Zoology Section to undertake research on the feeding behaviour of longidorid nematodes in relation to the histological changes induced in the roots of host plants.

Candidates should be qualified in nematology, zoology or botany. The minimum qualification is an Upper Second Class Honours degree and students graduating in 1979 will be eligible.

Application forms and further particulars are available from the Secretary of the Institute. The closing date for applications is March 31, 1979. 9978(F)

Firmenich

Many engaged in the manu-
industry of synthetic perfumes
opening for a

SENIOR TOXICOLOGIST

at its corporate headquarters in Geneva, Switzerland

Reporting directly to the corporate Management, the person appointed will assume the following major responsibilities:

- to represent FIRMENICH worldwide in matters of product safety,
- to provide a comprehensive advisory service to customers and government agencies, as well as to other companies in Firmenich's international Group,
- and, in general, to help formulate and implement Group policy for product safety, including the organization, supervision and interpretation of toxicity and dermatology tests carried out by independent laboratories.

The successful candidate will already have made a substantial impact in this field.

Ability to speak and write fluently in English as well as a good working knowledge of French are necessary, other languages being a further asset.

For more information please write in confidence to

Mr ERNEST K. WEBER, Director of Personnel

FIRMENICH SA - Département du Personnel
Case postale 238 - 1211 Genève 8

9925(A)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (University of London) Denmark Hill, London SE5 8RX LIVER UNIT

Applications are invited for the post of
RESEARCH ASSISTANT

in this busy multi-disciplinary unit, to participate in a project investigating immune responses to liver antigens in Liver disease.

Candidates should have some post-degree experience, possibly an M.Sc., and should be able to work independently without close supervision.

Salary will be on the nationally agreed salary scales for research staff, according to age, qualifications and experience.

Please apply, giving full curriculum vitae and the names and addresses of two referees to the Secretary of the Medical School at the above address. Telephone 01-274 6222, ext. 2040 for further details.

Closing date: March 29, 1977.
9911(A)

CHELSEA COLLEGE University of London Basic Medical Sciences Group DEPARTMENT OF PHYSIOLOGY

There is an opportunity for a young person with an interest in electronics to develop this interest and apply it to physiological problems. The post is for a **GRADE 4 TECHNICIAN** in the Department of Physiology to take part in teaching and research.

We should be pleased to hear from suitably qualified or experienced and interested persons who should, in the first instance, contact Susan Holly, Department of Physiology, Manresa Road, London SW3 6LX (01-352 6421) for further details and application forms.

The salary scale for this post is £3,420 to £3,867 per annum (under review), including £465 London Allowance.
9965(A)

Regional Cytogenetics Laboratory EAST BIRMINGHAM HOSPITAL BASIC GRADE SCIENTIFIC OFFICER

Applications are invited for the new post of Scientific Officer. Experience in cytogenetics desirable but not essential. Salary range depending on experience and qualifications—£2,991 to £4,899 per annum.

Application forms and job descriptions obtainable from Regional Cytogenetics Laboratory, East Birmingham Hospital, Bordesley Green East, Birmingham B9 5ST. Tel No 021-772-4311, Ext. 4354.
9947(A)

UNIVERSITY OF KEELE DEPARTMENT OF COMMUNICATION AND NEUROSCIENCE

Applications invited for research studentships in postgraduate Department engaged in research into sensory brain mechanisms. The Department has several interdisciplinary research groups working in such fields as visual and auditory psychophysics, visual and auditory neurophysiology, speech, blindness and deafness. Both experimental and theoretical work is carried out and specialised electronic, optical, acoustic, physiological and computing facilities are available in well-equipped laboratories.

A limited number of studentships are likely to be available for suitably qualified candidates who wish to proceed to an M.Sc. or Ph.D. degree. Interested students with backgrounds in biology, electrical or electronic engineering, mathematics, physics, physiology or psychology are asked to write to:

Dr D. H. Foster,
Department of Communication and Neuroscience,
University of Keele,
Keele,
Staffordshire
ST5 5BG.
9984(A)

UNIVERSITY OF THE WEST INDIES—JAMAICA Applications are invited for the post of PROFESSOR OF ANATOMY in the FACULTY OF MEDICINE

The appointee will be expected to give leadership in the teaching and research activities of the Department of Anatomy which prepares students for the M.B., B.S. degree of the University of the West Indies, and in the teaching of Surgical Anatomy to postgraduate students of Surgery. In connection with the implementation of the new curriculum, experience in teaching integrated courses in the pre-clinical and clinical subjects will be an additional asset.

Salary in the range, J\$19,326 to J\$22,578 p.a. (Medical), J\$17,166 to J\$21,252 p.a. (Non-medical) (£1 sterling=J\$3.42) F.S.S.U. Unfurnished accommodation will be let by the University at a rental of 10% of salary or a housing allowance of 20% of salary will be paid Study and Travel Grant. Family passages.

Detailed applications (2 copies) with curriculum vitae and naming three referees should be sent direct as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica.

Applicants resident in the U.K. should also send one copy to the Inter-University Council, 90-91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.
9912(A)

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF PATHOLOGY

Applications are invited for the office of

UNIVERSITY DEMONSTRATOR IN THE DEPARTMENT OF PATHOLOGY

Candidates should have a higher degree and appropriate research experience. The person appointed will be expected to demonstrate in general aspects of the pathological disciplines and to carry out research within the Division of Virology. Principal research interests of the Division are the biology of herpes and influenza viruses.

The initial appointment will be for three years from May 1, 1977. The pensionable stipend for a University Demonstrator will be on a scale of £4,133 rising by four annual increments to £5,129, with initial placing above the minimum where appropriate. The maximum tenure of a University Demonstratorship is five years. A grant is made towards removal expenses.

Candidates should send 12 copies of their application together with the names of not more than three referees to Mr G. R. ANDERSON, General Board Office, The Old Schools, Cambridge CB2 1TT, from whom further information can be obtained to arrive not later than March 28, 1977.
9919(A)

UNIVERSITY OF OXFORD NUFFIELD LABORATORY OF OPHTHALMOLOGY POSTDOCTORAL RESEARCH FELLOW and TECHNICIAN/RESEARCH ASSISTANT

required for three years for an investigation of the crosslink sites of collagen from normal and diseased sclera as part of a study of degenerative myopia, a common cause of blindness. Starting salaries up to £5,129 (postdoctoral) and £2,955 (technician grade 4). Experience of protein chemistry would be an advantage.

Further information from Dr J. J. Harding, Nuffield Laboratory of Ophthalmology, Walton Street, Oxford OX2 6AW to whom applications with curriculum vitae and the names of two referees should be submitted as soon as possible.
9935(A)

UNIVERSITY OF GLASGOW SENIOR LECTURER (POLLOCK LECTURER) IN CLINICAL PHARMACOLOGY

Applications are invited for the post of Senior Lecturer in the University Department of Materia Medica for a medical graduate with research and teaching experience in aspects of human pharmacology. It is expected that the successful applicant will establish and maintain an active research group. The present research interests of the department are cardiovascular and respiratory pharmacology and clinical aspects of pharmacokinetics and drug metabolism. Research interests outside these fields would not necessarily be a disadvantage. The department is responsible for teaching medicine and clinical pharmacology and therapeutics to medical students.

Salary will be fixed according to placement on the University scale for clinical teachers, maximum £12,068 (with consultant status).

Further details may be obtained from Professor John Reid, Department of Materia Medica, Stobhill General Hospital, Glasgow, telephone 041 55 0111.

Applications (12 copies), giving the names and addresses of three referees should be lodged with the Secretary of the University Court, (Room 18), University of Glasgow, Glasgow G1 8QQ, not later than March 30, 1977.

In reply please quote Ref No 9958(A)

UNIVERSITY OF DURHAM DEPARTMENT OF PHYSICS Applications are invited for a POSTDOCTORAL SENIOR RESEARCH ASSISTANTSHIP IN PHYSICS

for two years, starting as soon as possible after April 1, 1977, to work in collaboration with the Max Planck Institute for Radioastronomy in Bonn on the interpretation of the Galactic Continuum Radiation. Candidate should preferably have experience in cosmic rays, plasma physics or radio astronomy and an interest in computing.

Initial salary in the range £3,883 to £5,129 (under review), plus supernannuation.

Applicants (three copies) naming three referees should be sent by March 31, 1977, to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained.
10006(P)

**SENIOR/ASSOCIATE
SCIENTISTS
IN EXPERIMENTAL
CELL MORPHOLOGY AND
CYTOGENETICS**

The W. Alton Jones Cell Science Center is interested in expanding its research program by the recruitment of two new staff members at the level of SENIOR or ASSOCIATE SCIENTIST (FULL OR ASSOCIATE PROFESSOR EQUIVALENT). The Center is an operational unit of the Tissue Culture Association and has an active program of research on a variety of topics. It is concerned, as well, with advanced training and education involving cell tissue and organ cultures. The laboratories are modern, spacious, and well equipped. The Center has affiliations with the University of Vermont, SUNY at Plattsburgh, and the University of Rhode Island.

Suitable candidates will have a Ph.D. or M.D. and have made significant contributions to their chosen field. They should currently hold positions of not less than Assistant Professor or equivalent. It is expected that the candidates' research will involve the use of cell tissue or organ culture. It is expected as well that the candidates will have an established track record in obtaining research support from the funding agencies.

For further information on the Center and its programs, contact the Office of the Director, W. Alton Jones Cell Science Center. Resumes and names of four references to the Chairperson, Search Committee, In Care of W. Alton Jones Cell Science Center, Old Barn Road, Lake Placid, New York 12946.

The W. Alton Jones Cell Science Center is an Affirmative Action/Equal Opportunity Employer. Applications from women and minority groups are encouraged. 9922(A)

**THE AUSTRALIAN
NATIONAL UNIVERSITY**

Applications are invited from suitably qualified persons for appointment to the following position.

**THE JOHN CURTIN SCHOOL
OF MEDICAL RESEARCH
DEPARTMENT OF
MICROBIOLOGY
RESEARCH FELLOW**

The appointee will work with Dr G. Air and Dr W. G. Laver on the molecular biology of influenza virus variants. The project involves selection of influenza virus variants with monoclonal antibodies, then immunological analysis of their proteins and nucleic acids.

The appointment, which is funded by a grant from the National Institutes of Health, U.S.A., is for one year in the first instance with probable extensions for a further two years. It is hoped that the successful applicant would be able to take up the appointment in the near future.

Salary: Commencing salary will be in accordance with qualifications within the range \$A15,786 to \$A17,716. Current exchange rates are \$A1:56p:US\$1.13.

Other Conditions: A limited grant towards travel and removal expenses may be made. Assistance with housing is provided for an appointee from outside Canberra.

The closing date for receipt of applications is April 5, 1979. They should be sent to the Registrar, P.O. Box 4, Canberra, ACT 2600, Australia. 9981(A)

**POSTDOCTORAL
RESEARCH POSITION**

Atmospheric scientists with research interests in the photochemical modeling of the troposphere and stratosphere, the evolution of planetary atmospheres, and/or atmospheric radiative transfer are invited to apply for postdoctoral positions at the University of Florida. Applicants should contact W. L. Chameides, Department of Physics and Astronomy, University of Florida, Gainesville, Florida 32611. The University of Florida is an equal opportunity/affirmative action employer. 9969(A)

Wellcome

Electrochemist

Department of Physical Chemistry

Our Physical Chemistry Department has an unusual opportunity for a young graduate with a degree in chemistry or related subject. The department uses many sophisticated techniques in studying molecular structures and provides a service to other research areas.

Reporting to a research scientist, the successful applicant will assist in the application of electrochemistry to chemical, biochemical and biological problems. Experience, although desirable, is likely to be less important than a keen interest in the subject. Where it is appropriate, extra-mural training will be encouraged.

The Wellcome Foundation Limited is a major British-owned international pharmaceutical organisation. Our Research Laboratories are located in beautiful parkland surroundings in Beckenham, Kent. Conditions of employment include 4 weeks' holiday, pension scheme, subsidised canteen, excellent sports and social facilities and generous assistance with relocation expenses, where appropriate.

Please write, quoting reference number U/4, to

P. C. Anderson, Personnel Assistant,
The Wellcome Research Laboratories,
Langley Court, Beckenham, Kent BR3 3BS.

10008(A)

**POSITION AVAILABLE
THE INTERNATIONAL POTATO
CENTER**

APARTADO 5969, LIMA, PERU

Announces a postdoctoral position in tropical agronomy. Research emphasis will be on developing agronomic practices for growing potatoes in the hot humid tropics.

A successful candidate would be expected to have a background in agronomy and soils. Duties would include assessment of selected genotypes for adaptation and management of plants grown from both tubers and true seed. Early concentration of work would be in selected sites in Peru with the possibility of associated work in central America and the Philippines.

Applicants must have a Ph.D. in agronomy. The assignment is for three years. A knowledge of potato culture and the Spanish language is not essential but desirable. Please contact Dr S. Sadik, Head of the Physiology Department, for application forms (air mail). 9992(A)

**HARVARD MEDICAL
SCHOOL
NEUROBIOLOGIST**

The Department of Neurobiology is seeking a new faculty member at the Assistant-Professor level to begin 1979 or 1980. Applications from women and minority people are encouraged. Please send curriculum vitae and a brief outline of research plans, and have three letters of reference sent to Search Committee, Department of Neurobiology, Harvard Medical School, 25 Shattuck Street, Boston MA 02115. 9946(A)

**A well-known
PHARMACEUTICAL GROUP
located in Paris requires a
RESEARCH SCIENTIST**

for its
Mass Spectrometer Department
who will be responsible for:

- Operating a gas chromatograph-mass spectrometer—data system. He will also assist non-specialist users to operate the system and interpret their results.
- Carrying out routine maintenance, performing minor repairs and maintaining adequate stocks of spare parts.
- Purchasing and preparation of gas chromatography columns (both packed and capillary), selecting the appropriate column for each analysis and assisting in the development of analytical methods.

Applicants should be suitably qualified and have at least 2 years experience of analysis of trace metabolites by gas chromatography. Experience with mass spectrometry would be an advantage, as well as an ability to operate complex equipment. Fluent French not required but appreciated. English would be an advantage.

Applications will be treated in the strictest confidence and should be sent directly to 'Nature', who will forward. 'Nature', c/o Advertisement Department, Box 9997, 3 Dyma Buildings, Holborn, London EC1N 2NR. 9997(A)

**UNIVERSITY OF DURHAM
DEPARTMENT OF
PHYSICS**

Applications are invited from graduates, preferably with Ph.D. in the field of High Energy Astrophysics, for a

**POSTDOCTORAL SENIOR
RESEARCH ASSISTANTSHIP**

tenable for three years from as soon as possible. The successful candidate will join a research group working in experimental GAMMA RAY ASTROPHYSICS and should have some experience with balloon borne experiments. Salary on National Research Range 1A £3,883 to £6,555 (under review) plus superannuation.

Applications (three copies) naming three referees should be sent by March 26, 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. 9936(P)

**THE UNIVERSITY OF
MANCHESTER
LECTURESHIP IN
CHEMISTRY**

Applications are invited for the post of Lecturer in (Inorganic) Chemistry tenable from October 1, 1979. Preference may be given to applicants with research interests in the organometallic chemistry of the non-transition metals.

Initial salary within the range £3,883 to £4,831 per annum. Superannuation. Further particulars and application forms (returnable by May 1) from the Registrar, The University, Manchester M13 9PL. Quote reference 52/79/N. 10004(A)

THE OPEN UNIVERSITY
FACULTY OF SCIENCE

BIOLOGY TECHNICIANS

Biology Histology Technician

We require an experienced technician to take responsibility for organising and providing an histology service within the discipline. It is hoped that the post will also provide some photographic support.

Applicants should possess H.N.C. or equivalent qualification and at least six to ten years' experience in histology.

Salary on scale: £2,955—£3,402 p.a. (under review).

Ref: 3786

Biology Research Technician

The technician will be responsible for the day-to-day organisation of the Brain Research Group's main laboratory, and for assisting in the various research projects.

Applicants should possess H.N.C. or equivalent qualification and at least eight years' experience in biological or biochemical research laboratories.

Salary on scale: £2,955—£3,402 p.a. (under review).

Ref: 3787

Physiological Psychology Technician

The Science Faculty have a tenured vacancy in the Biology Discipline for a Technician to work with Dr. Geoff Eilon on investigations of the visual system. The technician will assume responsibility for the day-to-day running of a laboratory which uses electrophysiological recording and histological procedures to investigate visual projections in the avian forebrain. The experimental work involves the use of amplifiers, recorders, stimulators; programming and use of purpose built and general purpose microprocessor and general purpose computers; the use of a cryostat microtome and histological staining procedures; and the analysis and presentation of experimental data. The technician will be expected to contribute to all aspects of the research programme and become an integral member of the research group.

Applicants should have an H.N.C. or equivalent and 10-12 years' practical experience preferably in neurophysiological research.

Salary on scale: £3,654—£4,365 p.a. (under review).

Ref: 447

All three appointments are available with immediate effect.

Application forms and further particulars are available from The Recruitment Office (JD3786/3), The Open University, P.O. Box 75, Walton Hall, Milton Keynes, MK7 8AL or telephone Milton Keynes 63404; there is a 24 hour answering service on 63868.

PLEASE QUOTE THE REFERENCE NUMBER OF THE POST IN WHICH YOU ARE INTERESTED.

Closing date for applications: 23rd March.

9987(A)

Fife Health Board

Fife Area Laboratory

A vacancy has arisen for a

SENIOR GRADE BACTERIOLOGIST

in the Department of Medical Microbiology of Fife Area Laboratory. Candidates should be graduates with appropriate basic grade experience.

The Microbiology Department carries out diagnostic work for the hospitals, general practitioners and environmental health departments throughout Fife. The person appointed would be responsible to the Consultant Bacteriologist and should be able to assist in the preparation of reports on miscellaneous clinical specimens and in the supervision of the public health section. Experience in mycology and/or entomology would be desirable.

Further particulars and application forms available from the District Personnel Officer, East Fife District, Fife Health Board, Hayfield Road, Kirkcaldy (Telephone: Kirkcaldy 66141, Ext. 11) to whom they should be returned no later than March 31, 1979. The laboratory may be visited by arrangement with the Consultant Bacteriologist, Dr J. D. Barrie (Telephone: Kirkcaldy (0592) 61155, Ext. 350).

HEALTH CARE FOR A KINGDOM

9930(A)

UNIVERSITY OF ALBERTA DEPARTMENT OF ZOOLOGY EDMONTON, ALBERTA, CANADA

The Department will make tenurable appointments at the rank of Assistant Professor (minimally \$18,530.00 per annum, 1978-1979) on July 1, 1979. The Department well-developed Honours, Specialized and Graduate programmes, and present has 29 academic staff, graduate students, and 27 support staff. Applicants for the Assistant Professor positions must have a Ph.D. degree equivalent and should send a curriculum vitae, a brief statement of research objectives, a list of publications, the names of three referees to Dr F. Chia, Chairman, Department of Zoology, University of Alberta, Edmonton, Alberta, Canada T6G 2E9. deadline for receiving application May 1, 1979. The University of Alberta is an equal opportunity employer.

(1) Limnologist. Applicants with research interests in experimental quantitative limnology of lakes preferred. The person appointed expected to share in the teaching limnology and quantitative ecology to establish a strong research programme.

(2) Marine Invertebrate Zoologist. Individuals with research interests in any aspect of biology of marine invertebrates are invited to apply. Preference is given to applicants with work with molluscs or annelids. A person appointed is expected to share in the teaching of invertebrate zoology and marine biology and to establish a strong research programme.

9950(A)

UMIST APPOINTMENT OF POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a Postdoctoral Research Assistantship, financed by the Department of Energy, to investigate the thermal decomposition of kerogen and related natural materials extracted from shales removed during exploratory oil-well drilling. Experience of analytical procedures such as thermal analysis, gas-liquid chromatography and mass spectrometry are desirable, though not essential.

The appointment will be for a maximum of two years and the work will be under the supervision of Mr J. M. Bather.

The salary will be on a range, being £4,382 per annum for a Ph.D. aged 26.

Applications, with curriculum vitae and the names of two referees, should be sent as soon as possible to Professor P. G. Ashmore, Department of Chemistry, UMIST, P.O. Box 88, Sackville Street, Manchester M60 1QD 9982(A).

UNIVERSITY OF SURREY DEPARTMENT OF BIOCHEMISTRY SENIOR LECTURER IN NUTRITION

Applications are invited for the full time position of Senior Lecturer in the Department of Biochemistry. The person appointed will contribute to the undergraduate and postgraduate teaching and research in the Department. Preference will be given to candidates with a particular interest in clinical nutrition.

Applications must be graduates with a higher degree and a good research record. A medical qualification is desirable but not essential.

Salary will be within the range £7,506 to £9,263 per annum, according to qualifications and experience. Superannuation will be under U.S. conditions.

Further particulars about the post may be obtained from the Academic Registrar (LFG), University of Surrey, Guildford, Surrey GU2 5XH, or telephone 71281, ext. 452. Application from men and women in the form of a curriculum vitae together with the names and addresses of three referees should be sent to the above by March 23, 1979. 9937(A)

UNIVERSITY OF LEEDS Applications are invited for the post of Trainee Technician in the Food Technology Laboratories of the Procter Department of Food Science. In the first instance the post involves working under supervision with a wide variety of food processing equipment and instrumentation, preparation of food products for clinical and assisting with the running of classes. Later training in mechanical construction of research apparatus; use of electronics could form a significant part of the evolving du further education on a day release basis will be arranged.

Salary will be on the scale £1 to £2,199 per annum (under review depending on age). Applications, giving age and details of school record should be sent to Professor David Robinson, Procter Department of Food Science, The University, Leeds LS2 9JT. 9976(A)

UNIVERSITY OF DUNDEE

DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY

There is an immediate vacancy in the above Department, based at Ninewells Hospital and Medical School, Dundee, for a

RESEARCH TECHNICIAN

to join a group engaged in a study of oncofetal proteins. Experience of protein purification techniques and radioimmunoassay is desirable though not essential.

The post is financed from an external grant and is available in the first instance for a period of three years, with a possibility of renewal.

An applicant with an appropriate H.N.C. or equivalent qualification and at least eight years' relevant experience would be eligible for appointment at a salary of up to £3,720 per annum (under review) but an appointment at a lower grade could be offered to a less well-qualified and experienced applicant.

Applications, giving details of qualifications and experience and the names of two referees should be sent to The Secretary, The University, Dundee DD1 4HN by March 22, 1979. Please quote Ref: EST/121/79J. 9929(A)

PLANT BREEDING INSTITUTE

Maris Lane, Trumpington
Cambridge CB2 2LQ

HIGHER SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER

CYTOGENETICS DEPARTMENT

A research worker with experience in plant cytogenetics/cell biology is required for three years, commencing April 1, 1979, to participate in and be responsible for parts of a programme funded by the Ministry of Overseas Development to study the cytogenetics and cell biology of endo-perm development and grain quality in cereals with special attention to grain shrivelling in wheat-rye genotypes including triticale.

Candidates should have a 1st or upper 2nd class honours degree in an appropriate biological science and at least two years postgraduate experience in plant cytogenetics/cell biology or related research.

The appointment will be as Higher Scientific Officer (£4,101 to £5,448 per annum) or Senior Scientific Officer (£5,154 to £6,898 per annum). At least four years' relevant postgraduate experience is required for appointment as Senior Scientific Officer.

Applications with curriculum vitae and names and addresses of three referees should be sent to the Assistant Secretary (Establishment), quoting ref. CYT 47, by April 6, 1979. 9973(A)

THE UNIVERSITY OF LONDON

INSTITUTE OF OBSTETRICS AND GYNAECOLOGY AND

INSTITUTE OF NEUROLOGY

Postdoctoral post available for the study of endocrinological regulation of the reproductive system, with particular emphasis on the role of sex steroid. The successful candidate will be part of a research team working in new laboratories at the Institute of Obstetrics and Gynaecology, Hammersmith Hospital, Du Cane Road, W12, under the joint direction of Professor M. G. Elder and Dr L. Lim. Experience in molecular/cell biology, tissue culture and techniques associated with chromatin characterisation will be an advantage. Salary for this three-year appointment will be in the range of £3,883 to £4,882 per annum plus £450 London Allowance. Starting date can be negotiated (April to October 1979). Send applications with curriculum vitae to Dr L. Lim, Institute of Neurology, 33 Johns Mews, London WC1. 9988(A)

KUWAIT UNIVERSITY OF KUWAIT FACULTY OF MEDICINE

Medical Science and Clinical Appointments

Applications are invited for the following appointments in the Faculty of Medicine.

ANATOMY—Associate Professor. Candidates should have areas of specialisation in electron microscopy. The successful applicant's responsibilities will include directorship of the E.M. Unit, which is equipped with scanning and transmission microscopes. Assistant or Associate Professor. Preference will be given to candidates who have experience of teaching the anatomical disciplines to allied health students. The successful candidate will be responsible for co-ordinating allied health teaching in the Department of Anatomy.

COMMUNITY MEDICINE—Professor or Associate Professor in Epidemiology. Professor or Associate Professor in Public Health.

MEDICINE—Associate Professor. Candidates should be general physicians with a special interest in renal medicine and experience in haemodialysis, peritoneal dialysis and renal transplantation. Experience of renal morphology by light microscope would be an advantage.

MICROBIOLOGY—Professor or Associate Professor in Medical Bacteriology. Professor or Associate Professor in Clinical Bacteriology.

PATHOLOGY—Associate and Assistant Professors. Candidates should have experience in academic pathology, particularly in anatomic and histopathology. The successful candidates will have responsibilities in diagnostic pathology at the teaching hospital.

PHYSIOLOGY—Professor or Associate Professor in Neurophysiology.

Professor or Associate Professor in Endocrinology.

Professor or Associate Professor with specialisation in one of the following areas: Haematology, Gastrointestinal, Muscle or Cardiovascular.

SURGERY—Professor or Associate Professor in Urological Surgery.

Associate Professor in Traumatology and Burns.

Assistant Professor in Orthopaedics.

Applicants should possess a Ph.D. or equivalent higher medical qualification, and have conducted and published research in their field. Professors should have 14 years' experience, 4 as an associate professor or its equivalent, i.e. senior lecturer or reader. Associate professors should have 9 years' experience, 4 as an assistant professor or its equivalent, i.e. lecturer.

CONDITIONS OF APPOINTMENT

Salaries: Total monthly salaries will be within the following scales according to qualifications and experience (IKD—£1.80; US\$3.6 approx.).

Professors with clinical appointments: KD 755-860 (6 increments).

Professors medically or non-medically qualified with medical science appointments: KD 701-797 (6 increments).

Associate Professors with clinical appointments: KD 650-755 (6 increments).

Associate Professors medically qualified with medical science appointments: KD 605-701 (6 increments).

Associate Professors non-medically qualified: KD 575-665 (6 increments).

Assistant Professors with clinical appointments: KD 520-625 (6 increments).

Assistant Professors medically qualified with medical science appointments: KD 484-580 (6 increments).

Assistant Professors non-medically qualified: KD 460-550 (6 increments).

Clinical supplements: In addition to the above university salaries there will be a monthly clinical supplement paid by the Ministry of Public Health for medical school staff with clinical service commitments. These will be within the following scales:

Professor and Chairman: KD 200-250 (5 increments).

Professor: KD 150-200 (5 increments).

Associate Professor: KD 100-150 (5 increments).

Assistant Professor: KD 75.

Gratuity: There is a gratuity of one month's basic salary for each year employed which is payable on termination of contract.

Housing: Suitably furnished, air-conditioned accommodation, electricity and water are provided free of charge.

Medical Care: Free, comprehensive treatment is available in Kuwait under the State Health Service.

Travel: Airline tickets are provided from the country of recruitment for the appointee, spouse and up to 3 dependent children under 20 years. Thereafter return tickets are issued annually to the country of origin. On termination of contract, tickets are provided to the country of recruitment. A baggage and freight allowance is also provided. In addition, travel expenses for attending one scientific meeting a year are paid by the University.

Vacation: Sixty days paid annual leave as well as various official holidays.

Education: This is provided free in state schools where the instruction is in Arabic. Staff who have to send their children to non-Arabic schools in Kuwait will have the cost of up to a maximum of three met by the University.

Taxation: There is no income tax in Kuwait. Currency is freely transferable without restrictions.

Further details about these appointments and the method of application can be obtained from: The Dean, Faculty of Medicine, University of Kuwait, P.O. Box 5969, Kuwait.

Completed applications must be received by no later than April 25, 1979.

9993(A)

POSTDOCTORAL RESEARCH ASSOCIATE POSITION

To study role of poly(adenosine diphosphoribose) synthesis in eukaryotic DNA repair processes. Experience diphosphoribose) synthesis in eukaryotic DNA repair processes. Experience with DNA repair, nucleic acid and chromatin chemistry desirable. Send curriculum vitae and references to Dr N. A. Berger, Hematology-Oncology Division, Jewish Hospital, Washington University School of Medicine, 216 S. Kingshighway, St. Louis, Missouri, 63110.

Equal Opportunity Employer. 9860(A)

INSTITUTE OF OBSTETRICS AND GYNAECOLOGY MEDICAL LABORATORY SCIENTIFIC OFFICER

There is a vacancy at the Institute of Obstetrics and Gynaecology, Queen Charlotte's Maternity Hospital for a Medical Laboratory Scientific Officer for chemical investigation of lung surfactant in children with cystic fibrosis. The appointment will be for two years. Qualifications: Degree/H.N.C. in Chemistry or Biochemistry. Salary £3,243 to £3,720 per annum including London Weighting.

Applications with the names of 2 referees to:

Miss C. E. Parkinson,
Institute of Obstetrics and Gynaecology,
Queen Charlotte's Maternity Hospital,
Goldhawk Road,
London W6.

9986(A)

Scottish Institute of Agricultural Engineering

Head of Soils Section

Senior Scientific Officer/ Principal Scientific Officer (Ref. AG/18'B)

Re-advertisement

Applications are invited for the post of Senior Scientific Officer/Principal Scientific Officer to lead a team investigating the effects of agricultural machinery on the physical properties of field soils with particular reference to cultivations, zero-tillage and compaction.

Qualifications

A first or upper second class honours degree, and preferably a higher degree, or equivalent qualifications in a relevant branch of science or engineering. The applicant should have had considerable experience of research in soil physics or soil mechanics.

Salary Scales

Appointment in the grade of Senior Scientific Officer (£5,154-£6,898) or Principal Scientific Officer (£6,609-£8,461) according to qualifications and experience. Non-contributory superannuation.

Application forms and further information from the Secretary, Scottish Institute of Agricultural Engineering, Bush Estate, Penicuik, Midlothian, EH26 0PH, to whom applications should be submitted by April 2, 1979.

9917(A)

THE BRITISH INDUSTRIAL BIOLOGICAL RESEARCH ASSOCIATION

Histopathologist

The BIBRA Research Laboratories undertake research studies in the assessment of environmental chemicals for possible toxicity and are seeking a GRADUATE PATHOLOGIST/BIOLOGIST to strengthen their Pathology Department.

The position would involve the histopathological examination of tissues from safety evaluation studies and participation in fundamental research programmes designed to improve methodology and to give a better understanding of toxic effects.

The Department has modern facilities for histopathology, histochemistry and electron microscopy; the development of relevant research interests within these fields would be encouraged.

Applicants should be veterinary, medical or biology graduate with experience in pathology. Salary will be in accordance with age and experience.

Applications with curriculum vitae should be sent to:

**The Secretary
The British Industrial Biological
Research Association
Woodmansterne Road
Carshalton, Surrey SM5 4DS**

9964(A)

MEDICAL RESEARCH COUNCIL Clinical and Population Cytogenetics Unit Edinburgh

MOLECULAR OR CELL BIOLOGIST

A vacancy exists for a molecular or cell biologist to work with a small team studying the molecular organisation and function of human chromosomes. One area of interest involves the use of restriction enzymes in the study of DNA composition and variation in man and experience with relevant techniques, or in the handling of cultured mammalian cells and chromosomes, would be an advantage, but not essential. Candidates should have a Ph.D. or equivalent and the appointment will be made at an appropriate level on Medical Research Council scientific scales. Applications, including names of two referees, should be sent to the Administrative Officer, M.R.C. Clinical and Population Cytogenetics Unit, Western General Hospital, Crewe Road, Edinburgh EH4 2XU, by March 31, 1979.

9834(A)

THE UNIVERSITY OF CALGARY

Faculty of Medicine

DIVISION OF PHARMACOLOGY & THERAPEUTICS

Applications are invited for a position as an Assistant Professor commencing September 1, 1979.

Duties will include teaching in both the undergraduate and graduate educational programme.

Successful applicant must be an active researcher.

Salary and rank according to qualifications and experience.

Nominations and/or applications will be received by:

**Dr. S.H. Roth
Acting Head
Division of Pharmacology and Therapeutics
Faculty of Medicine
The University of Calgary
Calgary, Alberta
T2N 1N4**

9934(A)

THE UNIVERSITY OF MANCHESTER RESEARCH ASSOCIATE IN HIGH ENERGY PHYSICS

Applications are invited for the post of Research Associate with the experimental high energy physics group at the University of Manchester. The duties would be to work on the operation of an experiment on PETRA in the DESY Laboratory, Hamburg, and also to work on the analysis of the data obtained. It would be necessary to spend extended periods in Hamburg. Duties to start as soon as possible. Salary within the range £3,883 to £4,631 per annum. Superannuation. To make application (or to enquire further) please write to Professor P. G. Murphy, Department of Physics, The University, Manchester M13 9PL, including full curriculum vitae and the names of three referees (if applying without further enquiry). 9960(A)

UNIVERSITY OF THE WEST INDIES—BARBADOS Applications are invited for the post of LECTURER/ ASSISTANT LECTURER IN PHYSICS

The appointee will be expected to assume duty by September 1, 1979.

Salary scales: Lecturer, BDS\$19,071 to BDS\$29,799 p.a.; Assistant Lecturer, BDS\$15,480 to BDS\$16,974 p.a. (£1 sterling=BDS\$4.00.) F.S.S.U. Unfurnished accommodation will be let by the University at a rental of 10% of salary. A housing allowance of 20% of salary is payable to staff who make their own housing arrangements. Family passages. Study and Travel Grant.

Detailed applications (2 copies) with curriculum vitae and naming three referees should be sent direct as soon as possible to the Secretary, University of the West Indies, P.O. Box 64, Bridgetown, Barbados.

Applicants resident in the U.K. should also send one copy to the Inter-University Council, 90-91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 9913(A)

UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF ZOOLOGY

The University invites applications for the post of
LECTURER

in the Department of Zoology, tenable from October 1, 1979. Candidates should possess a higher degree or equivalent research experience, and preference will be given to those with experience in invertebrate neurophysiology. Applicants with other qualifications, particularly in ecology or entomology may also be considered.

Salary will be at an appropriate point on the Lecturers' scale: £3,883 to £7,754 per annum, according to age, qualifications and experience. Membership of the appropriate University superannuation scheme will be required.

Further particulars may be obtained from the Senior Assistant Registrar, The University, 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU, with whom applications (three copies), together with the names and addresses of three referees, should be lodged not later than April 9, 1979. Please quote reference N. 10003(A)

BLOOD GROUP REFERENCE LABORATORY SCIENTIFIC OFFICER

A graduate is required to assist Dr C. M. Giles in reference work related to blood transfusion. This laboratory is recognised by the World Health Organisation as a Collaborating Laboratory for Reference and Research in Blood Grouping and many varied problems are investigated. Opportunities are available for study for a higher degree. Experience in the field of blood transfusion desirable.

Applications in writing, with curriculum vitae to Miss K. Lomas, Blood Group Reference Laboratory, Gatliff Road, off Ebury Bridge Road, London SW1W 8QJ. 9972(A)

ROYAL POSTGRADUATE MEDICAL SCHOOL PEPTIDE SECTION (DEPARTMENT OF CHEMICAL PATHOLOGY) TECHNICIAN/SCIENTIFIC OFFICER

required in the Peptide Laboratory to take part in the synthesis of novel peptide hormone analogues. Applicant should possess H.N.C. or a degree in chemistry or biochemistry and have experience and/or interest in organic synthesis. The post is tenable for 1 months in the first instance, with possibility of further extension.

Salary within the range £3,646 to £4,199 placing dependent on qualifications and experience.

Application forms may be obtained from the Personnel Office, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 0HS quoting reference number 4/203/N. 9810(A)

UNIVERSITY OF OXFORD CLARENDON LABORATORY Temporary Teaching Appointment in Physics (Electronics)

Applications are invited for a five year appointment from October 1979, on the University Lecturer scale £3,883 to £8,257 per annum (under review), the duties being to lecture in electronics, assist with demonstrating and engage in advanced study and research. There are likely to be opportunities for the person appointed to assist also with college teaching. Further particulars may be obtained from Professor E. W. J. Mitchell, Clarendon Laboratory, Parks Road, Oxford OX1 3PU, to whom application should be sent by April 9. 9971(A)

UNIVERSITY OF SOUTHAMPTON INSTITUTE OF SOUND AND VIBRATION RESEARCH EXPERIMENTAL OFFICER

required by Industrial and Machinery Noise Group, to undertake design and testing of machinery components. The applicants should be graduate engineer with practical workshop and drawing office experience.

Salary scale £3,384 to £5,367 per annum (under review) plus U.S.S. benefits.

Applications, giving a brief curriculum vitae and the names of three referees, should be sent to D. A. S. Copland, The University, Southampton SO9 5NH, quoting reference 184/A/1. 9942(A)

RESEARCH ASSOCIATE PHYSIOLOGY AND BIOPHYSICS

Position available immediately concerning integrative studies of vascular smooth muscle and hypertension. Candidate must have Ph.D. or equivalent, and record of accomplishments in muscle structure or function or hypertension. Experience desirable in methods associated with one or more of the following: electrophysiology; microcirculatory hemodynamics. Send resume and names of three referees to: Dr William Halpern, Department of Physiology and Biophysics, University of Vermont, Burlington, Vermont 05405 U.S.A.

An Affirmative Action Employer. 9953(A)

UNIVERSITY COLLEGE DUBLIN

Applications are invited by the Governing Body of the College for the following full-time statutory appointment:

PROFESSORSHIP OF GEOLOGY

Prior to application, further information (including application procedure) should be obtained from the Secretary and Bursar, University College, Belfield, Dublin 4. Telephone enquiries: 693244, Ext. 431.

The closing date for receipt of completed applications is THURSDAY MARCH 29, 1979. 9921(A)

THE UNIVERSITY OF LEEDS

Department of Animal Physiology and Nutrition

Applications are invited for the post of LECTURER in the above Department, available from October 1, 1979. The appointment will be made for a fixed term period of three years. Applicants must have experience in either the nutrition or physiology of farm livestock.

Salary on the scale for lecturers £3,883 to £7,754 (under review), according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 61/5/D. Closing date for applications May 14, 1979.

9928(A)

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR

Applications are invited for the post of

RESEARCH ASSISTANT

in the College's Department of Zoology, to assist in the experimental investigation of foraging behaviour in marine invertebrate predators.

The appointment, funded by the N.E.R.C. and commencing September 1, 1979, will be for three years, and will be at an initial salary of £3,384 per annum.

Applications (two copies), giving details of qualifications and experience, together with the names and addresses of three referees, should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, from whom further particulars may be obtained.

Closing date for applications: March 26, 1979.

9939(A)

UNIVERSITY OF CAMBRIDGE ANIMAL PRODUCTIVITY/ NUTRITION

Applications invited for a University Demonstratorship in Animal Productivity/Nutrition in the Department of Applied Biology. Qualifications—good Honours degree, research experience in some aspect of animal productivity related to nutrition and competence in biometry. Salary in scale £4,133 to £5,129. Pensionable under U.S.S. Limited contribution to removal expenses. Further details from and applications including full personal particulars, list of publications and names and addresses of not more than three referees to the Secretary, Faculty of Biology 'A', Appointments Committee, Department of Applied Biology, Pembroke Street, Cambridge CB2 3DX not later than March 31, 1979.

9974(A)

UNIVERSITY OF EDINBURGH DEPARTMENT OF ZOOLOGY LECTURER

(Sub-Department of Parasitology)

Applications are invited for the post of Lecturer in the Department of Zoology (Sub-Department of Parasitology). Candidates must be prepared to teach helminthology. Salary scale £3,883 to £7,754 per annum (under review), with placement according to qualifications and age, and with superannuation benefit.

The successful candidate will be expected to take up duty on October 1, 1979.

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, with whom applications (six copies), giving the name of two referees, should be lodged not later than April 10, 1979. Please quote Reference 1028.

9998(A)

POSITION AVAILABLE THE INTERNATIONAL POTATO CENTER

APARTADO 5949, LIMA, PERU

Announces a postdoctoral position in the utilization of true seed for the production of consumer potatoes. Research will involve studies of pollination and fruit development, harvesting, seed extraction, dormancy and germination.

The utilization of true seed as a means of propagating consumer potatoes is a relatively new and challenging field. The successful candidate must be innovative in research and have a sound botanical background. A knowledge of embryogenesis and seed physiology as part of a Ph.D. background would be essential.

The position is for a period of three years. A knowledge of Spanish is desirable but not essential. Please contact Dr S. Sadik, Head, Department of Plant Physiology, for application forms (air mail).

9991(A)

GUY'S HOSPITAL MEDICAL SCHOOL (University of London) JUNIOR LECTURER

in Biochemistry required as soon as possible.

Applicants should have a Ph.D. in Biochemistry. Duties include teaching biochemistry to Medical, Dental and B.Sc. students, and Chemistry to Preliminary students, and the successful applicant will be expected to initiate and carry out a research project of his own choosing.

The appointment will be for three years in the first instance. Salary range £4,655 to £5,604 plus £450 London Allowance and Superannuation. Further details may be obtained from Professor A. T. Diplock (01-407 7600, Ext. 2365). Application forms obtainable from the Dean, Guy's Hospital Medical School, London Bridge, London SE1 9RT. The closing date for applications will be April 6, 1979.

9955(A)

INDUSTRIAL TOXICOLOGIST

Bio-Research Laboratories Ltd. is the major contract research company in Canada and has immediate openings for industrial toxicologists who will become part of a multidisciplinary team of scientists involved in the evaluation in laboratory animals of the toxicological effects of drugs, food additives, pesticides and other industrial chemicals. In general, the responsibilities of the toxicologists will include design, supervision, interpretation and reporting of a variety of toxicological research including teratology, reproduction, subacute, chronic and carcinogenicity studies involving laboratory rodents, dogs and subhuman primates.

Prospective candidates should have a background in veterinary medicine, pharmacology, physiology or biochemistry, preferably with postgraduate training at the Ph.D. level and a minimum of two years' experience in industrial toxicology.

Our new modern laboratories are located in pleasant surroundings in a western suburb of Montreal. Salary and other benefits will be commensurate with training and experience. Please forward detailed résumé, including references and salary history and requirements to:

Dr. B. G. Procter,
Director of Toxicology,
Bio-Research Laboratories Ltd.,
87 Senneville Road,
Senneville, Quebec, Canada.
H9X 3R3

BIO-RESEARCH LABORATORIES LTD

9970(A)

FELLOWSHIPS and STUDENTSHIPS

As a pharmaceutical Research Institute, we are a subsidiary of the worldwide SANDOZ-Group. Our objective is the discovery of new approaches to the therapy and prophylaxis of infectious diseases.

Currently, we offer a

POSTDOCTORAL FELLOWSHIP

in our Department of Bacteriology. This opening is concerned with the influence of antibiotics on phagocytosis, and the efficacy of antibiotics against bacteria within phagocytes.

The successful candidate will find excellent working conditions in well equipped laboratories. The appointment will be for an initial 2-year period. We offer an attractive salary. Travel expenses from and to the country of origin will be paid.

We invite applications from **biochemists**, **cell-biologists** or **microbiologists**. Experience in antibiotic research will be helpful but is not essential.

Please send application including curriculum vitae and credentials to

Dr. N. Zacherl, Personnel Manager,
SANDOZ Forschungsinstitut,
A-1235 Wien, Brunner Strasse 59,
Austria.

9918(A)

FELLOWSHIPS and STUDENTSHIPS

Industrial Fellowship

Organic Chemistry

Merck Sharp & Dohme Research Laboratories invite applications for an Industrial Fellowship, tenable for two years at their Development Laboratories at Hoddesdon, Hertfordshire.

The Organic Chemistry Department carries out a wide range of assignments concerned with the syntheses of compounds for clinical and pharmacological investigations and also for medicinal chemistry research programmes.

The position provides a unique opportunity for a young post-graduate chemist to gain experience in the pharmaceutical industry of working from small scale bench experiments through to pilot scale preparations.

The successful candidate will have a research degree in Organic Chemistry (probably Ph.D.) with some experience in physical-organic chemistry.

Further details and an application form may be obtained from: The Personnel Manager.

Merck Sharp & Dohme Limited,
Hertford Road, Hoddesdon, Herts EN11 9BU.
Tel: Hoddesdon 67272 ext 377.

9994(E)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF EARTH SCIENCES

O.D.M. RESEARCH STUDENTSHIPS IN GEOPHYSICS

Applications are invited for two Ph.D. research studentships, funded by the Ministry of Overseas Development, to undertake the regional gravity survey of western and southern Sudan. Certain seismological investigations will also be carried out in conjunction with the survey. The projects are to investigate the structure of the Jebel Marra volcanic centre and the surrounding Precambrian basement which is mainly obscured by more recent sediments.

Applicants should have a good background knowledge of geophysics at undergraduate or M.Sc. level and possess full driving licences.

The studentships are for three years starting October 1, 1979. Requests for further information and applications, including a full curriculum vitae and the names of two referees should be made to Dr G. W. Stuart, Department of Earth Sciences, The University of Leeds, Leeds LS2 9JT.

9938(F)

UNIVERSITY OF NOTTINGHAM

and

Tropical Products Institute

RESEARCH STUDENTSHIP

Silage from Tropical Fish

Applications are invited from those holding at least a 2(i) Honours B.Sc. degree or an M.Sc. degree, in biochemistry, chemistry, animal science or food science, for a T.P.I. Research Studentship tenable at the University of Nottingham.

The successful applicant will be based in the Food Science Laboratories of the Department of Applied Biochemistry and Nutrition, Sutton Bonington, and will be required to work full-time on a programme for the development and nutritional testing of silage from tropical fish and register for a research degree of the University of Nottingham. During the tenure of the studentship the appointee, who will be selected following an interview, will probably be required to spend a period of time overseas.

Those interested should write, in the first instance to:

The Secretary,
University of Nottingham,
School of Agriculture,
Sutton Bonington,
Loughborough,
Leicestershire LE12 5RD.
Telephone: Kegworth 2386

10005(F)

UNIVERSITY OF SHEFFIELD

DEPARTMENT OF CERAMICS, GLASSES AND POLYMERS

Research Studentships in the Physics and Chemistry of Materials

The Department expects to be able to offer a number of Research Studentships this year over a wide range of topics in the science and technology of materials.

Two C.A.S.E. studentships, a Harwell-sponsored studentship and an independently financed studentship are already available. Further C.A.S.E. studentships which may become available shortly are for work in association with a number of major companies in the chemical, electrical and materials manufacturing industries. They are likely to be of interest to graduates in physics, chemistry, materials science and, in one case, applied mathematics or theoretical physics.

Further information from the Head of Department, Professor J. P. Roberts, Department of Ceramics, Glasses and Polymers, "Elmfield", Northumberland Road, Sheffield S10 2TZ.

Quote Ref. 255/ . 9937(F)

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

(University of London)

DEPARTMENT OF BIOCHEMISTRY AND CHEMISTRY

Applications are invited for two POSTDOCTORAL RESEARCH FELLOWSHIPS

in BIOCHEMICAL ENDOCRINOLOGY supported by the Cancer Research Campaign and The Wellcome Trust to work with Dr B. A. Cooke on the hormonal control of normal and neoplastic Leydig cells. Experience of cell culture and hormone receptors would be an advantage.

Commencing salary within range £3,909 to £4,655 plus £450 London Allowance.

Further information from the School Secretary, R.F.H.S.M., 8 Hunte Street, London WC1N 1BP (or telephone 01-837 5385, ext. 54), to whom applications should be submitted as soon as possible, quoting reference CRC/W. 9924(A)

NEW ZEALAND UNIVERSITY OF CANTERBURY

Christchurch

Applications are invited for a UNIVERSITY POSTDOCTORAL FELLOWSHIP

in the

DEPARTMENT OF CHEMISTRY

Applicants must possess a Ph.D. or equivalent degree, preferably followed by some research experience. Applicants should state the field of research in which they would intend to work during the period of the Fellowship.

Applications close on April 30, 1979. The emolument will be NZ\$8,500 per annum. Fellowships are tenable for one year.

Further particulars and Conditions of Appointment may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordo Square, London WC1H 0PF. 9961(E)

CITY OF LONDON POLYTECHNIC

DEPARTMENT OF GEOLOGY

SIR JOHN CASS'S FOUNDATION

RESEARCH FELLOWSHIP IN GEOLOGY

A newly created postdoctoral Fellowship funded by the Sir John Cass' Foundation is being offered in the field of Sedimentology. This 3-year post will be available from September 1 1979, with a salary in the range of £3,747 to £4,203, plus £474 (London Allowance).

Applications (giving age, qualifications, experience and intended research programme, together with the name and addresses of two referees) should be made as soon as possible to Dr R. R. Skelhorn, Department of Geology, City of London Polytechnic, Walburgh House, Bigland Street, London E1 2NG. 9914(E)

IMPERIAL CANCER RESEARCH FUND

RESEARCH FELLOWSHIP

A Postdoctoral Fellow required for an appointment for three years. The work will be on the mechanisms by which host cells control the expression of tumour-inducing viruses. Familiarity with nucleic acid hybridisation and allied techniques would be an advantage but is not essential. Salary with entry according to qualifications and experience within range £5,332 to £6,530, inc. L.A.

Further information from Dr John Wyke (01-242 0200, ext. 267). Applications with curriculum vitae and names of two referees, should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX by April 13, 1979 quoting ref. 141/142/79. 9951(E)

RESEARCH FELLOWSHIP IMPERIAL CANCER RESEARCH FUND

A postdoctoral medicinal chemist is required to join a multi-disciplinary group working on the synthesis and evaluation of potentially selective antitumour agents. The project encompasses both the induction of differentiation and also the exploitation of the characteristic biochemical properties of certain specific tumours to achieve selective toxicity. The preferred candidate would be primarily a good synthetic chemist who has had previous experience of working in the field of biologically active compounds.

Appointment will be for three years. Salary with entry according to qualifications and experience within the range £5,332 to £6,530 inc L.A.

Further information from Dr A. M. Creighton (01-242 0200, Ext. 284). Applications with curriculum vitae and names of two referees should be sent to The Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX, quoting reference 139/140/79 by April 13, 1979. 9952(E)

FEBS FELLOWSHIPS

FEBS Fellowships are to support short-term (not longer than two months) visits by members of any FEBS Constituent Society to laboratories in another country in the FEBS area for the purpose of carrying out experiments with special techniques or other forms of scientific collaboration or advanced training, and especially to support developments arising at short notice.

Fellowships will not be granted to attend courses, symposia, meetings or congresses.

Fellowships will cover both travel and subsistence.

Information and details of making an application may be obtained from:

Professor G. Dirheimer,
FEBS Fellowships Officer,
Institut de Biologie Moléculaire et Cellulaire du CNRS,
15 rue Descartes,
67084 Strasbourg Cedex,
France. 9933(E)

UNIVERSITY OF YORK POSTDOCTORAL FELLOWSHIP

An M.R.C. Fellowship is available for a joint project between the Cancer Research Unit and the Department of Chemistry. The research topic will be concerned with studying the metabolic activation of aflatoxins, a group of carcinogenic human food contaminants. The proposed studies will concern the reasons for species differences in susceptibility to these compounds. Applicants should have a sound background in foreign compound metabolism and preferably some experience in identification of metabolites.

The appointment will be for three years from June 1, 1979 or as soon as possible thereafter and the salary will be within Range 1A of the scales for research staff, starting at £3,883 per annum (under review), plus USS.

Three copies of applications, with curriculum vitae and the names of two referees, should be sent by April 6, 1979 to the Registrar, University of York, Heslington, York YO1 5DD. Informal enquiries to Dr Colin Garner, Cancer Research Unit. Please quote reference number 11/6099. 9959(E)

SCHOLARSHIPS

THE AUSTRALIAN NATIONAL UNIVERSITY SCHOLARSHIPS FOR Ph.D. DEGREE COURSES

Persons who hold, or expect to hold, a bachelor degree with at least upper second-class honours or equivalent from a recognised University and who have a capacity for research, are invited to apply for Australian National University Ph.D. Scholarships, tenable over a wide range of subjects in the Humanities and the Physical, Medical, Chemical, Biological, Earth and Social Sciences. Scholarships are available in any of the departments or units of the Institute of Advanced Studies which consists of Research Schools of Physical Sciences, Biological Sciences, Social Sciences, Pacific Studies, Chemistry, Earth Sciences and the John Curtin School of Medical Research, of the School of General Studies (Faculties of Arts, Asian Studies, Economics, Law and Science); or in one of the University Centres.

Scholarship Benefits: The basic stipend payable is \$4,700 per annum (tax free) with additional allowances for dependants and housing assistance for married scholars. In addition, return economy-standard air fares and a grant towards removal expenses are normally provided. (The latter will not be provided for Australian citizens overseas who are eligible for Commonwealth Government Research Awards.)

Tenure: Scholarships are normally tenable for three years and may be taken up at any time of the year.

There is no set closing date, but applicants from outside Australia are advised to apply at least six months before they expect to be available to take up a scholarship, if offered.

Full particulars and application forms are available from the Registrar, The Australian National University, P.O. Box 4, Canberra, A.C.T., 2601, or from the Association of Commonwealth Universities (Apsu), 36 Gordon Square, London WC1H 0PF. 9985(E)

A Comprehensive International Two-day Conference NEW TECHNOLOGIES IN THE HEALTH CARE INDUSTRY San Francisco—May 21-22 London —June 11-12

This market-oriented conference for the corporate executive in planning and research and development will focus on future market possibilities.

Brochure available from the organisers: ROBERT S. FIRST, INC., 19a Avenue Marix, 1050 Brussels. Telephone: (02)512 50 63. Telex: 22859. 10007(C)

UNIVERSITY OF DURHAM DEPARTMENT OF GEOLOGICAL SCIENCES CONOCO ADVANCED COURSE STUDENTSHIP IN GEOPHYSICS

Candidates intending to seek a career in the oil industry are invited to apply for the above studentship (equivalent to a N.E.R.C. Studentship) to attend the one-year M.Sc. Advanced Course in Geophysics from October 1979.

Candidates should hold, or expect to obtain in the Summer of 1979, at least a 2(i) Honours degree. Preference is given to candidates with single or joint honours in Geology. An adequate background in Mathematics, preferably to first year university level, is required.

Applications should be submitted before April 30, giving full academic qualifications and the names and addresses of at least two referees, to Dr. R. E. Long, Department of Geological Sciences, University of Durham, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars of the course and the studentship may be obtained. 9989(D)

FEBS ADVANCED COURSES

No. 65. "The Control of Glycogen Metabolism"
Brussels, Belgium,
5-7 September 1979

The Course, organised by H. De Wulf, H. G. Hers, L. Hue and G. van de Werve, will cover the properties of enzymes involved in glycogen metabolism as well as aspects specific to muscle, liver, adipocytes and leucocytes. It will include lectures by invited speakers and presentation of posters by registered participants. A limited number of these posters will be subjected to general discussion. Registration fee: about \$50. For further information, contact Professor H. G. Hers, Université Catholique de Louvain and International Institute of Cellular and Molecular Pathology, UCL 75.39-75 avenue Hippocrate, B-1200 Brussels, Belgium. The deadline for applications and abstracts is May 15, 1979.

No. 67. "Recombinant DNA"
Zagreb, Yugoslavia,
15-27 October 1979

A Laboratory Course for 25 participants. The experimental program will include: In vitro recombination of DNA segments with plasmid and viral vectors. Cloning in *Escherichia coli* and *Bacillus subtilis*. Selection and screening of cloned recombinant DNA. Characterization of cloned recombinant DNA. Registration fee \$100. Applications (by April 30, 1979) and info: Dr Vjera Zaga, Dept. of Experimental Biology and Medicine, "Ruder Boskovic" Institute, P.O.B. 1016, 41001 Zagreb, Yugoslavia.

No. 64. "Modern Methods of DNA Sequencing"
Gliwice, Poland,
5-10 November 1979

This Course for 15 students aims to disseminate within European research laboratories the two basic methods of DNA sequencing: the Maxam-Gilbert technique and Sanger's inhibitor chain-termination technique. Advanced studies will cover sequence organization of DNAs from various sources. Further information and application forms (to be returned by May 31, 1979) are available from the organizers Dr M. Chomay/Dr S. Szala, Dept. of Tumour Biology, Institute of Oncology, 44-100 Gliwice, Poland. 9932(D)

COURSES, CONFERENCES AND SYMPOSIA (Continued)

FIFTH EMBO ANNUAL SYMPOSIUM NUCLEIC ACID-PROTEIN INTERACTIONS

October 12–15 inclusive

EMBL Heidelberg

In addition to members of the Organising Committee invited speakers include:

J. Abelson (La Jolla); T. Bickle (Basel); H. Bujard (Heidelberg); P. Chambon (Strasbourg); R. Flavell (Amsterdam); C. Guthrie (San Francisco); S. Harrison (Harvard); C. Helene (Orléans); H. Hoffmann-Berling (Heidelberg); A. Landy (Brown); A. McPherson (Pennsylvania); M. Ptashne (Harvard); M. T. Record (Madison); H. Saedler (Freiburg); A. Schmitz (Geneva); J. Sperling (Rehovot); G. Stöffler (Berlin); F. W. Studier (Brookhaven); E. Vinuela (Madrid); J. C. Wang (Harvard); W. Wintermeyer (Munich); C. Yanofsky (Stanford).

The eight Plenary Sessions will cover Model Systems; Viruses; Chromatin; Polymerases; Regulatory Signals on DNA; Cleaving, Processing and Modifying Nucleic Acids; Ribosomes and tRNA; New Frontiers.

The Symposium will be held at the European Molecular Biology Laboratory Heidelberg with registration on Thursday, October 11. Plenary sessions will be held in the mornings and afternoons of October 12–15 inclusive. The Symposium banquet will be held on the evening of October 15. Poster sessions will be arranged; applicants wishing to present a poster should submit a title and an abstract of 1–2 pages. Participants will be accommodated in two hotels on downtown Heidelberg, and transportation to the meeting will be arranged.

The registration fee is DM 80.00 and includes daily lunches and the banquet but neither hotel charges nor evening meals.

Applications including a curriculum vitae should be sent to Dr. J. Tooze, Executive Secretary, European Molecular Biology Organisation, Postfach 1022.40, 69 Heidelberg 1, FRG, by May 31, 1979. Since the number of participants is limited to 200 the Organising Committee will notify those who have been accepted in August.

Organising Committee: D. Crothers (Yale); J.-P. Ebel (Strasbourg); A. Klug (Cambridge); C. Kurland (Uppsala, Chairman); J. Miller (Geneva); H. Schaller (Heidelberg); J. Tooze (Heidelberg, Secretary); C. Weissmann (Zürich). 9943(M)

THE NEW YORK ACADEMY OF SCIENCES

Conference on

REGULATORY FUNCTIONS OF INTERFERONS

New York City, October 23–26, 1979

The New York Academy of Sciences is planning to sponsor a four-day Conference on interdisciplinary aspects of interferon research. The Conference is co-chaired by J. Vilcek (New York University), I. Gresser (Institut de Recherches Scientifiques sur le Cancer, Villejuif) and T. C. Merigan (Stanford University). The Conference will cover: immunoregulatory actions of interferons; regulatory effects of interferons in lymphocytes, macrophages and other cells; interferons as lymphokines; cell growth inhibitory and antitumor actions of interferons; genetics of the interferon system; purification and properties of interferons; molecular mechanisms of interferon action.

To supplement invited lectures, the organising committee will accept suitable poster session presentations. The deadline for the submission of abstracts to be considered for poster presentation is June 1, 1979. The abstracts should include the name of the author(s), institution and 100–200 word summary of work to be presented in the poster. Send abstracts for poster session and inquiries about details of the program and registration to:

Conference Director,
New York Academy of Sciences,
2 East 63rd Street,
New York, NY 10021.

50th ANNIVERSARY SYMPOSIUM

THE JACKSON LABORATORY

July 17–20, 1979

A CENTURY OF MAMMALIAN GENETICS AND CANCER, 1929–2029:

A VIEW IN MIDPASSAGE

TOPICS include *Genes and Chromosome Organisation, Differentiation, Immunogenetics, Inherited Diseases, Cancer*. Elizabeth Russell, Chairman.

For program and registration information, write to Symposium Committee, The Jackson Laboratory, Bar Harbor, Maine 04609, USA. May 1 registration deadline. 9995(M)

LEUKAEMIA RESEARCH FUND

International Research Symposium on PHILADELPHIA CHROMOSOME POSITIVE LEUKAEMIAS

will be held at the Royal College of Physicians, London, on **Tuesday, April 10, 1979**. Registration fee (includes lunch) £6.

Apply for details and registration form to:

**Leukaemia Research Fund,
43 Great Ormond Street,
London WC1N 3JJ
Tel: 01-405 0101**

UNIVERSITY OF LONDON

ROYAL POSTGRADUATE
MEDICAL SCHOOL

M.Sc. DEGREE COURSE IN EXPERIMENTAL

PATHOLOGY (TOXICOLOGY)

Applications are invited for the above one-year, full-time course which is being offered from October 3, 1979.

Applicants should possess a first degree in medicine, veterinary medicine or appropriate science subjects.

A limited number of M.R.C. course studentships are available.

Further details and application forms are available from the

Assistant Secretary (Registrar)
Royal Postgraduate Medical School
Hammersmith Hospital
Du Cane Road
London W12 0HS
(Tel: 01-743 2030, ext. 263)

The closing date for applications is Thursday, May 31, 1979. 9916(D)

UNIVERSITY OF LONDON KING'S COLLEGE

M.Sc.

in

HUMAN AND APPLIED PHYSIOLOGY

A one-year course to train graduate in measuring and studying the physiological functioning of man in normal and abnormal environments. The course would equip students to specialise in the applications of physiology to man in industrial, Service and clinical situations and the teaching of human physiology. Topics studied include:—basic measurements; life support systems; exercise; locomotor postural; climatic; high altitude and hyperbaric physiology.

October 1, 1979 to September 30 1980.

Applicants should have a good degree in Physiology or be medically qualified.

Further details and application form from: Dr S. Rowlands, King's College, Strand, LONDON WC2R 2LS, quoting reference N 1/3.

Closing date for applications: March 31, 1979. 9811(D)

Volumetrics Pipettors

50 μ l, 100 μ l

Accuracy and reproducibility better than $\pm 1\%$. Priced as low as \$2.00 ea.

VOLUMETRICS WORK STATION holds 2 Pipettors and 250 tips (shown without dust cover).

Pasteur + Plus

DISPOSABLE PLASTIC TRANSFER PIPETTES

Regular
Ultra lean-tubed

A safer alternative to the glass pipette. No bulb to leak, safe one time use without risk of contamination.

For volumes up to 3 ml. 21 to 24 drops/ml delivery.

Tips

We carry a full line of disposable polypropylene tips for our own and many other pipettors.

Ultipettes

Excellent for Pasteur pipetting. Five adjustable models: to 1 ml, to 2 ml, to 5 ml, (with air bleed for optional use); 2 ml and 5 ml models also available in PTFE for acids and solvents.

Finnpipettes

OVER 70,000 IN USE WORLD WIDE.

Accurate, reproducible adjustable micropipetting. 5 instruments to cover the range from 1 μ l to 5,000 μ l.

L-Cysteine [³⁵S] >500Ci/mmol Translation Grade

Cysteine, L-[³⁵S]-

>500Ci/mmol
10mM dithiothreitol in water,
shipped in dry ice.

NEG-022T 1mCi 5mCi

Not for use in humans or clinical diagnosis

Each lot is pre-tested for biological activity in a cell-free translation system, and the incorporation curve is provided with the shipment.

Increased Protein Labeling Capacity

Paired with our translation grade Methionine, L-[³⁵S] at >500Ci/mmol (NEG-009T), the new Cysteine is useful in producing even hotter proteins.

IMMUNOCHEMICALS FROM MILES?

YES, INNOVATIVE AND PROVEN PRODUCTS FOR RESEARCH AND CLINICAL LABORATORY USE.

Perhaps you think of Miles as a place to get the unusual, like antiserum to rat IgE or equine IgM.

Perhaps you know we offer a wide selection of human protein antisera encompassing newer products, such as antisera to myoglobin, ferritin and β -2 microglobulin, as well as established antisera to immunoglobulins, α -1 antitrypsin and other major serum proteins.

Of course, you may not associate us with immunochemicals at all... We think you should.

Author Index

The new Barbican Centre is much more than one of the most modern conference centres in one of the world's most historic cities. It's an Arts Centre, too.

For example, the Royal Shakespeare Company will have its new permanent home in the Barbican. So will the London Symphony Orchestra. And the Guildhall School of Music and Drama. There will be a new Art Gallery—one of the biggest in London. Culture in plenty.

And as for commerce, all the great City of London institutions such as the Bank of England, the Stock Exchange, the money markets, insurance

companies—they're all within easy reach. And history is everywhere. The Tower of London. St Paul's Cathedral. Guildhall. The Monument. The whole atmosphere of the City reflects a long and glorious history. But to get back to conference facilities. If you look at the captions below you'll find most of the details you need. But for fuller details, just contact our Conference Director. He'll be glad to help. With completion in 1980, we're already taking bookings for 1981 and onwards. The Barbican Centre, 11 Cromwell Tower, The Barbican, London EC2Y 8DD England. Telephone: 01-638 4141.

London's new Barbican Centre— surrounded by centuries of history, commerce and culture.

A display and exhibition area with a total of 88,000 square feet (8,100 square metres).

The Barbican Conference Hall comfortably seats 2,000 delegates.

A variety of lecture theatres, seminar and committee rooms to take anything from 5 to 275 delegates.

The Film Theatre—with all the most up-to-date audio visual equipment—seats 300 people.

The Barbican Theatre seats 1,150

All in all, the Barbican Centre is flexible enough to house any kind of conference you wish to plan. Try it and see.

REPRINTS

High-quality reprints of any paper published in **Nature** can be bought in bulk quantity (50 or more).

This service is not restricted to authors.

Typically, 100 2-page reprints would cost £18.90 (£23.50 by airmail); 1,000 would cost £41.35 (£89.70 by airmail). Covers can also be supplied.

Why not write to us for a quotation?

London WC2R 3LF
England

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures.

Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines.

If possible; exp (*a*) is preferred to *e^a* if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976).

now you can measure testosterone and dihydrotestosterone separately or together

Our new RIA kit is the simplest and fastest available for the assay of testosterone and dihydrotestosterone, separately or together in research applications in a wide range of biological samples.

To assay both androgens together a high specific activity tritium label gives the assay a very sensitive detection limit of 3 pg dihydrotestosterone per incubation tube. Also, a wide range of concentration levels can be assayed, up to 400 pg testosterone and 800 pg dihydrotestosterone per incubation tube.

Separation of the two androgens is achieved without the need for column chromatography by the use of a novel oxidation step which destroys the testosterone present. The assay of the unaffected dihydrotestosterone is achieved with a simple protocol incorporating a short incubation time of 2½ hours. Standards for both androgens are provided. Accurate results are obtained easily and quickly.

The machinery works—does it produce the goods?

IN 1972 the British government published a White Paper 'Framework for Government Research and Development' which recommended re-structuring of financial support for R & D. The White Paper sprang largely from a report written by Lord Rothschild, and proposed, amongst other things, that support for applied R & D, whether conducted within or outside government departments should be controlled by the customer/contractor principle: departments as customers define their needs; contractors advise on the possibility of meeting these needs and undertake the work; and customer and contractor keep in close contact to ensure that objectives remain obtainable at a reasonable cost.

Of course, much departmental in-house R & D had always run along these general lines, but the controversial element of the Rothschild recommendations was that a substantial amount of work supported by Research Councils, particularly in their own establishments, should no longer be funded through the Science Vote (and thus ultimately by the Department of Education and Science) but be paid for by customer departments; research councils would continue to provide management for such activities, but the customers would control their direction. Customer departments were expected to acquire a Chief Scientist who would strengthen the department's ability to commission research widely. Chief Scientists would play an active role in research councils and also in the newly-formed Advisory Board for the Research Councils (ABRC) which took on a role of supervising the councils. The reorganisation could be seen as a corrective to a tendency for work in research council establishments to cover roughly the fields of interest of government departments without any obvious way for departments to express this interest and guide research, beyond gentle persuasion.

Has it worked? The Lord Privy Seal, quaintly entrusted with overseeing research and development policy co-ordination, has just issued, with a little help from his friends, a review of the R & D machinery as it now stands (Cmd 7499; £1.25). The answer, no great surprise, is that whilst there are still defects and weaknesses in the system, there is no call for further wholesale change in the arrangements.

The areas still needing attention, says the report, include the following. First, there is a danger that research councils (and, it could have been added, individual establishments such as the Institute of Geological Sciences) become so loaded with commissioned research that they lose independence to pursue their own ideas. The report sounds a particular warning over the Agricultural Research Council, which receives more than half its income from the Ministry of Agriculture, Fisheries and Food for contract work. Second, the report points out that the Department of Health has until recently had difficulties in fulfilling its role as informed customer in biomedical research, owing to the conflicting demands of health and social services research on the limited expertise available in the department. Third,

ABRC has, up to now, been too preoccupied with the Rothschild reorganisation and then with allocation of diminishing resources to devote enough time to "more general problems which arise from, or affect, the scientific activities of the government, research councils or universities". It is to be 'invited' to review its working methods to free more time for broader questions.

The machinery works tolerably well. But what of the product? It is not unreasonable to ask not only whether the right sort of bureaucratic connections are now being made, but also whether these are bearing fruit in terms of research results of real value. On this the report is silent—two paragraphs, entitled 'The Dissemination and Utilisation of Results' comprise only generalities. Of course it is much more difficult to reach objective judgements on whether customers and the nation are really profiting from the new arrangements than it is just to verify that the arrangements meet general approval. Of course some of the timescales involved are too long for answers to be given yet. But without a dispassionate and rigorous assessment (and more than the department's point of view would have to be taken into account), it is impossible to be sure that all the time and effort actually bears fruit. The report claims to "try to assess whether the scientific activities financed by the government are now properly related to national need." It does not do this; someone should.

Less publicised amongst Rothschild's recommendation was that scientists in government should be enabled to play a larger role in working out departmental needs and in policy formulation by improving their managerial skills. This was to be achieved by courses in management training, competitive transfer of scientists to the Administration Group and the stimulation of staff interchange with universities and industry. Here the report valuably notes that there has been miserable failure. Few civil service scientists are interested in jumping to administration and few are prepared to do even a short time outside the service—the inter-change unit was disbanded last year.

It is difficult to know what is wrong. Scientists are often to be heard grumbling that they don't get as many chances as administrators—"always on tap, never on top". Yet there are always apparently reasons why they never take the plunge. If they stay in science, however, many lose their enthusiasm and spend an unhappy ten or twenty years up to retirement.

Individuals have to recognise that no switch in career can be made without at least temporary inconvenience and struggle. Government has to recognise that private industry offers financial inducements to people it wants to move, and that it cannot expect much success without offering the same. A review of these manpower problems of the scientific civil service, under the chairmanship of Dr Martin Holdgate of the Department of the Environment, is just about to start to cover this ground yet again. □

Science exchanges at stake in SALT talks, says adviser

A FAILURE to agree on the terms of a strategic arms limitation treaty between the United States and the USSR could jeopardise the future of scientific exchanges between the two countries, Dr Frank Press, director of the Office of Science and Technology and science adviser to President Carter, said last week.

In a speech designed to encourage support in the scientific community for the second Strategic Arms Limitation Treaty (SALT 2), the terms of which are expected to be agreed shortly, Dr Press told a meeting organised by the State Department that if SALT 2 succeeds, other forms of cooperation—such as scientific exchange—could succeed. But if the agreement failed, it was difficult to see much chance for other kinds of cooperation to succeed.

"I am not saying we should sign SALT—any SALT agreement—just or even primarily to insure the future of scientific cooperation and exchange with the Soviet Union. What I am saying is that it is a clear side-benefit of SALT", he said.

Dr Press's remarks came as the administration is preparing a campaign to convince members of Congress,

some of whom have already expressed their opposition, to ratify the treaty once the terms are agreed by both sides.

Scientists had an important role to play in the debate on SALT, since before the Senate and the public could judge the treaty, they would have to understand it, he said. "Your views will carry special weight in the public mind on an issue like this. I urge you to play an active role and share your expertise and understanding of SALT with friends and colleagues."

An illustration of the type of issue involved in the forthcoming debate arose last week when Senator Henry Jackson announced that he was not going to support SALT 2, partly because he felt that the loss of US monitoring posts in Iran made the terms of the proposed treaty impossible to verify.

Earlier in the week, however, Mr Herbert Scoville, formerly deputy director responsible for scientific affairs in the Central Intelligence Agency, disputed this claim. He said that redundancy in the current monitoring system, as well as other verification systems such as satellites, was adequate

to ensure compliance, even with the loss of the Iran stations (much of the equipment from which is now being moved to Turkey).

Some scientists have expressed concern that, although they agree with Dr Press on the need to participate in wide public discussion of the technical aspects of the proposed SALT agreement, it will be difficult to do this adequately when much of the necessary information on, for example, monitoring techniques remains classified.

"I am quite prepared to encourage debate on the treaty provided that we can get the information on which such discussions can be based. But if we cannot get the necessary information, then I would be very doubtful about taking it up," Mr William Carey, executive officer of the American Association for the Advancement of Science, said last week.

Others are concerned that, in this eagerness to make the proposed treaty acceptable to a wide constituency in the Senate, President Carter is prepared to give the go-ahead to a range of new military technologies, thus doing little to curb the overall arms race.

David Dickson

Europe plans to predict earthquakes

EUROPE is to embark on a programme of earthquake prediction involving the collection of data on the ground and from satellites. A preliminary outline for the programme was drawn up by scientists attending a seminar organised by the European Space Agency and the Parliamentary Assembly of the Council of Europe in Strasbourg last week.

The programme is intended to monitor the Alpine-Mediterranean belt which runs from Turkey through Italy and Spain to the Azores. It is initially proposed to run from 1980-91 by which time a fully operational system of data-collecting stations should be in existence.

The possibility of an earthquake prediction programme for Europe was first raised last October at the Parliamentary Assembly of the Council of Europe by the chairman of the Assembly's Committee on Science and Technology, who comes from the Friuli region of Italy which suffered severe earthquakes in May 1976. He felt that because several of the member states of the Council of Europe are prone to earthquakes, efforts to predict them should be coordinated. Support from other parliamentarians was sufficient to warrant a detailed debate and the set-

ting up of last week's seminar.

The idea is to augment and co-ordinate earthquake prediction programmes already existing in individual states. The ground-based programme will involve collecting geophysical, geodesic, astronomical, geochemical and other data from 150 fixed stations and several mobile ones. Existing stations will be redefined to form part of a network and new ones will be built.

The space-based programme will involve imaging from satellites and aircraft, including laser-ranging and, later on, satellite-assisted very long base interferometry. Future geostationary satellites will be equipped with relevant imaging instruments. One of the aims is to draw a new seismic map of Europe.

The seminar decided that the European-Mediterranean Seismological Centre (EMSC) at Strasbourg should collect, analyse and interpret the data. It also recommended that a European Association for Earthquake Prediction be set up to run the programme, although initial responsibility will probably rest with the working party on geodynamics of the Parliamentary Assembly of the Council of Europe in conjunction with the European Space

Earthquake in Italy: a stimulus for the programme.

Agency, the European Seismology Commission and the Europe-Mediterranean Seismology Centre.

No estimate of the cost has yet been made. Rather than a pool of money being available for the programme as a whole, ground-based projects will probably be paid for by the state in whose territory they are and space-based projects will probably be built and paid for under ESA's new and optional Earth-oriented research programme.

Judy Redfearn

OTA faces another summer of uncertainty

David Dickson discusses the continuing troubles of the Office of Technology Assessment, whose third director in six years resigned earlier this month

LAST Thursday the twelve US Congressmen who make up the board of the Congress' Office of Technology Assessment met for the second time in eighteen months to discuss how to choose a new director for the agency.

The meeting was made necessary by the surprise resignation of OTA's current director Dr Russell Peterson (above), who took on the position last January. A chemist by training, Dr Peterson spent 26 years with the Du Pont Company, heading its research and development division until he was elected governor of the State of Delaware in 1968. In 1973 he was made chairman of the Council on Environmental Quality, which he left to set up a citizen's lobby group New Directions before moving to OTA.

Stating that his varied experiences in private and public life have "led me to prefer an advocacy role rather than an advisory one," Dr Peterson announced that he had accepted an invitation to become the president of the National Audubon Society, a body of 400,000 members whose main role is to protect the bird life of America.

In his 13-month occupancy at OTA, Dr Peterson has done much to put the agency on its feet, following a shaky start plagued by internal and external political wrangles. By streamlining day-to-day management, introducing clear hierarchies of responsibility, and other such moves, he has restored both OTA's reputation and its morale.

However it is no secret that Dr Peterson's strong views, both about how OTA should be run—he demanded, and got, complete authority to hire and fire staff—and on its role with respect to Congress, have themselves caused considerable friction (his resignation came not long after a particularly bitter board meeting in January).

Given that the aspects of Dr Peterson's personality which have exacerbated this friction are those that have helped place OTA on a more stable and effective footing, his departure has once again raised the

question of whether OTA—however desirable its objectives—can in fact function in the way that it was intended to do by Congress.

The Office of Technology Assessment was established by statute as an advisory arm of Congress in 1972. Its function is to help legislators anticipate and plan for the long-term consequences of technological applications, and to examine the many ways in which technology affects peoples' lives.

Few challenge the need for such analysis. And although the quality of the agency's reports have varied enormously, some—such as those on solar energy, on medical technology, and on a proposed coal slurry pipeline—have been widely praised, and played an important role in the development of legislation.

The big stumbling block has therefore not been whether, but how, such studies should be carried out. Under the first chairman, Mr Emilio Q Daddario—himself a former Congressman—OTA stayed close to the political process. This meant good contact with the political community; but the price was fierce political infighting that frequently spilled into the press, and consequently drained credibility from the agency's reports.

Under Dr Peterson's leadership the agency has, some feel, gone to the other extreme. By refusing to accept direct political pressure, he has eliminated many festering sores; but the criticism is that he has spent too much time telling Congress what it should be interested in, rather than listening to its demands.

Dr Peterson himself has strong, if controversial, views about technology assessment and its goals. "If we are to ensure change for the better, we must become skilled and successful architects of change. In today's interdependent world, that requires a holistic perspective—a comprehensive, world-wide, long-range view," he said.

The most obvious manifestation of this "holistic" approach has been an ambitious priority-setting exercise which

he set in motion last year. Over 5,000 people were asked to suggest critical technological issues facing the US and the world; to 1,530 topics suggested for study were added a further 2,875 extracted from the published literature. Synthesis and elimination by OTA staff led to a final list of 30 ranked items.

Few complained about the outcome. Of the final list, seven items were immediately selected by the board as areas for study, and three more subsequently added; these included alternative national energy futures, regulation and technological innovation, and the effects of nuclear war.

However a certain amount of resentment was caused by the fact that the exercise was initiated by Dr Peterson largely on his own initiative, and that by placing heavy emphasis on the exercise, he had shifted away from what they see as OTA's prime responsibility, namely responding to demands relating to specific legislation.

The issue of short-term versus long-term studies is endemic to discussions over the role of OTA, and is far from satisfactory resolution. And the need to maintain a balanced strategy places heavy responsibility on the shoulders of the director. The consensus in Washington seems to be that the new director needs the political skills and sensitivities of Daddario, the vision and managerial capabilities of Peterson, and a professional reputation respected in the scientific and technical community.

The task of finding a successor is therefore a daunting one. So much so that some are questioning whether OTA might not benefit from some structural change; for example, it could be more formally separated from political decisions by reducing the involvement of the 12 board members and increasing the independence of the director (a possible model might be Congress' General Accounting Office).

Many would welcome such a move, possibly with the idea of a scientific Brookings Institute in mind. Others, however, see it as a betrayal of the ideals that established OTA as a research tool forming part of, not a commentator on, the political process.

As usual in such cases, the last word may rest with those who hold the purse strings. Appropriations committees in both House and Senate are looking closely at OTA's budget request for 1980; possible cuts of \$2 to \$3 million (in a request of \$11.2 million), are being rumoured, and the final decision may well reflect Congress' reaction to the choice of a new director. It promises to be another long, hot summer for OTA. □

How the CIA backed research on mind control

David Dickson reports on recent revelations about the Central Intelligence Agency's support for university research

IN THE late 1950s and early 1960s, the US Central Intelligence Agency mounted a comprehensive and well-planned effort to encourage university scientists to carry out research that would, the agency hoped, lead directly to techniques for controlling the human mind.

According to previously classified documents, the agency was responsible for initiating or supporting research that led subsequently to important contributions in various fields of behavioural science, including sociolinguistics, psychotherapy and personality assessment.

And in an effort to legitimise its interest and obtain access to leading investigators, the agency financed a funding organisation that provided grants to a number of prominent members of the scientific community—including Carl Rogers, B. F. Skinner and Professor Hans Eysenck—even though the researchers were frequently unaware of the true source of their support.

The details of the CIA's involvement in these fields, described as helping to "liberate the behavioural sciences from the world of rats and cheese", are provided in a book which has just been published in the US by Mr John Marks, a former Senate aide and State Department official. (The book will appear in the UK later this year.)

Using documents obtained through the Freedom of Information Act, Mr Marks has put together a detailed picture of how the agency used the academic community in its search for the holy grail: a technique that would provide sufficient manipulation of the human mind to eliminate uncertainty from the intelligence business.

Many of the more bizarre, farcical or outrageous aspects of this pursuit have since received wide publicity. These range from experiments that switched the East coast academic community on to LSD, to the construction of a bugged San Francisco brothel (and included a scheme to make Fidel Castro's beard fall out).

But behind these there was, as Mr Marks shows, a closely considered plan for deriving, through the extension of conventional research techniques and the often unknowing cooperation of university scientists, the type of information that the CIA could use for controlling the behaviour of its agents and others.

Much of this research was financed through an organisation known as the Society for the Investigation of Human

Ecology, set up at Cornell University in 1955 under the guidance of Dr Harry Wolff, professor of neurology and psychiatry, who was later to become president of the American Neurological Association.

Dr Wolff's aim, which received considerable sympathy in various academic circles of the time, was to provide a framework for the multi-disciplinary study of man in relation to his environment. The CIA's interest was sufficient for it to provide 90% of the society's funding until, having separated from Cornell in 1957 to obtain "more established stature in the research community", the organisation was folded in the mid-1960s.

Some of the research funded through the society had a direct and obvious relation to the agency's interests. It provided Wolff himself with a research grant of \$74,000 to study the factors that cause men to defect from their countries and cooperate with a foreign government.

In other cases, the concerns were more basic. Professor Charles Osgood, for example, who had asked the CIA to support his research into the way people in different societies express similar feelings, received \$192,975 over five years through the society. He later completed his influential work on cross-cultural meaning on a grant from the National Institute of Mental Health.

In some cases, the CIA used research grants explicitly to build up the prestige of the Human Ecology Society. Thus the society provided \$26,000 to Professor Eysenck of London University to support his work on motivation; the agency accepted that the research would have "no immediate relevance to agency needs", but the society took funding credit for nine of his publications in its 1963 report.

"It's news to me", said Professor Eysenck. Often the research workers

were unaware of the source of the majority of the society's funds; some were told that the money came from rich New York doctors or Texas millionaires. "I don't like secret involvement of any kind. I can't see why it could not have been open and above board", says Professor B. F. Skinner, who received \$5,000 towards the research leading to his book *Freedom and Dignity*.

But as well as providing academic respectability, funding of research through the society allowed the CIA legitimately to approach "anyone in the academic community", as one source put it. Thus in a move that Mr Marks describes as "turning scholars into spies", the society provided \$15,000 towards a tour of the Soviet Union by ten prominent psychologists (only one of whom knew of the agency's involvement), and CIA officials debriefed the group on its return.

Support for university behavioural research was curtailed in the mid-1960s. However, in contradiction of testimony later given to Senate committees, the research itself was continued, although with a greater emphasis on more direct ways of influencing behaviour, such as inserting electrodes in the brain. (At one point, agency scientists considered the potential of genetic manipulation: "The rest of the world didn't ask until 1976 the type of questions we were facing in 1965", one agency source is quoted as saying.)

Mr Marks admits that much of the research which the CIA sponsored led to important contributions to accepted academic knowledge—possibly because the agency was free to take imaginative leaps denied to more conservative (or more democratic) agencies. But he is uncompromising in criticising the ethical basis under which many of the experiments were carried out. (This was not always the agency's fault; some scientists had to be restrained from taking their experiments on, for example, sensory deprivation to their "terminal" conclusion.)

"We as a country can defend ourselves without sending our own scientists—mad or otherwise—into a hidden war that violates our basic ethical and constitutional principles. . . . The time has come for the United States to lead by example by voluntarily renouncing secret government behavioural research", Mr Marks writes in his conclusion. □

The Search for the 'Manchurian Candidate': The CIA and Mind Control by John Marks (Times Books, New York, \$9.95). The British edition will be published by Penguin.

UK atomic authority 'was a great mistake'—Benn

THE creation of the United Kingdom Atomic Energy Authority in 1955 "hived off policy formation as well as execution". It was, in retrospect, "a great mistake", the UK Secretary of State for Energy, Mr Tony Benn, said last week.

In a *Nature* interview with Mr Benn and his chief scientist, Sir Hermann Bondi, Mr Benn criticised the constitution of the UKAEA—under which research on waste management was relatively neglected for a long period. "If—in the creation of the Authority—the government had hived off Harwell and Aldermaston as research establishments, but kept the leading figures in nuclear policy within government, their relationship with the minister would have been very much closer than it is", he said.

Mr Benn has been minister in charge of the Authority from 1966 to 1970 and from 1975 to now. He believes "we have suffered" from its political autonomy.

In fact Sir John Hill, chairman of the United Kingdom Atomic Energy Authority, sought an interview with Mr Benn last week to discuss how to improve the flow of information between the Authority and the minister. After the meeting, Mr Benn announced that he would be sending a letter to Sir John outlining "a new list of areas of legitimate ministerial interest".

"It's not a question of control", said Mr Benn "it's a question of the integration of this very high technology with the democratic process. There are some very serious defects, but they don't arise from wickedness. They arise from the nature of the problem.

"Sir John came and said 'I tell you everything. What's wrong?'; but actually the problem of observing, watching, and connecting all these issues that a minister has, is quite different from the role of a manager of an authority. I am interested in all sorts of things—like, for example, what was that explosion in Russia in 1958? What happened to the 200 tonnes of uranium lost in the Mediterranean? I am interested in the movement of plutonium nitrates from Dounreay to Windscale, the real role of fusion, and all the areas relevant to the International Fuel Cycle Evaluation Programme. I try to preside over a range of issues as intelligently as I can, and need to keep informed on them all."

A second institutional problem, said Benn, is that in an agency set up to develop nuclear power the consequential effects of the technology "have tended to become subsidiaries to the agency's prime purpose". In practice,

Tony Benn: seeking more information on nuclear power

however, the effects have turned out to be very important.

"Where you fail to institutionalise basic conflicts that ought to exist in political discussion, then what happens is that the conflicts are solved at the Deputy Secretary level instead of at the Cabinet level. You must institutionalise the control of nuclear power to the point where all real arguments come to the top."

"The issues are enormous", said Mr Benn. He lists among them "the flow of information, the role of secrecy" in all high technology industries—including oil and gas—not just nuclear power. Also civil liberties, "where when you centralise, you then find the package deal includes a degree of intervention in civil liberties which is potentially unacceptable. All these things need to be brought out."

"In the end—however complicated a technology is—the public have the right in a democratic society to say no, as we've seen in Austria and very nearly saw in Switzerland. There is no escape from the ultimate provision of consent. The job of a minister is not to mystify, or to over-simplify, but to clarify, so that people know what they are doing. And you have to do it much earlier in the case of high technology."

"If it's a case of a road—do you want the M3 to go through Aldershot or not?—then you have a planning inquiry; but in the case of fast breeders, or nuclear power, or any other high technology, decisions will be taken that pre-empt things that will not happen for 10 or 20 years."

"The role of a minister as a public interrogator, who goes on asking questions, and then publishes the questions and invites the debate, is essential—otherwise you wake up one day and find that all the key decisions were taken 10 years ago. Then people get frustrated, they get violent, they get pessimistic, they get cynical. That is destructive of the whole democratic process, and it undermines the technology on which you have spent billions

and billions of pounds."

"This is my main interest in politics: how to get democratic control established effectively over areas where high skill, high complexity, high security, make the normal operations of democracy very very difficult."

Sir Hermann Bondi thought that the history of nuclear waste management "was an extremely interesting case". What the UKAEA had failed to foresee, said Sir Hermann, was not the need for the management of wastes, "but that there should be public anxiety about it".

In a sense the issue fell between two stools: "it fell into that gap between the institution and the politicians, so that neither saw that there would be an issue on which the public would become excited. The institution felt that all that the public were worried about was getting the power out of the plug cheaply, and they felt that technically the waste problem was soluble, so that there was no hurry yet to solve it."

Mr Benn illustrated the point with a story about cufflinks. "Have you had the British Nuclear fuel cufflinks?" he asked Sir Hermann. Sir Hermann had not. "I was sent a set of cufflinks by BNFL" said Benn "which is an ordinary set of cufflinks, but on the side where you would have a piece of jade or whatever, is a little brown, glass thing, and the card with them said 'These cufflinks represent how much vitrified waste you would generate through household usage in a year if all electricity were generated by nuclear power'. This was to show how small the problem is. They ignored the fact that they have got to last 20,000 years, and that even 40 million cufflinks make a pile." The idea that waste could be tackled by "the PR techniques of cufflinks" was "absolutely fantastic. I've never worn them because they are to me such a precious example of the wrong way of presenting a problem to people."

Robert Walgate

news in brief

SRC action puts new pressure on short-term contract workers: The Science Research Council has proposed a shift in funding emphasis from staff to equipment in a letter, written, "as a matter of urgency", to senior administrators at universities, colleges and polytechnics. Expressing concern about possible expenditure cuts arising from "the present industrial troubles", the council considers that the best way it can help research at present is to encourage applications for equipment. The council says "we cannot make additional major commitments to research grants which involve substantial expenditure over a period of several years such as those in which the provision of staff plays an important part". It urges speedy application before the next grant closing date of 1 April. [Brian Oakley, SRC secretary, says it is only partly a worry about the economic climate that has caused the shift in emphasis. "Good applications depend on good people and using the money for a three-year grant splurge will not bring in the young people that are necessary to swell the number of good applications."] Research workers on short-term contracts have expressed dismay at the SRC's action. "By spending money in this way, the SRC ignores the proven quality of senior researchers as shown by successive grant renewals through the highly competitive SRC grant selection process. Instead, the council is adopting a cynical policy of recruitment of younger workers who are cheaper and less knowledgeable about the system", says Robert Golub of the committee for long-term non-tenured faculty at Sussex University.

Levich appointed to New York chair: Professor Benjamin Levich (left), the Soviet dissident who was allowed to leave last year after a long campaign on his behalf by western scientists, has been appointed to the Albert Einstein chair in science at the City College of the City University of New York. Professor Levich has already become affiliated to Tel Aviv University in Israel. Dr Robert J. Kibbee, chancellor of City University, said last week that the appointment "helps to im-

plement an earlier agreement of cooperation reached between City University and Israeli universities." City College hopes to establish with Tel Aviv University a joint institute for applied chemical physics under Professor Levich's leadership.

Congolese geneticist still detained: This month marks the second anniversary of the arrest of Pascal Lissouba, agricultural geneticist and former Prime Minister of the Congo. Since his arrest and summary trial in March 1977, Professor Lissouba has been held under harsh conditions in the prison at Ouessou in the northern Congo. He is known to be seriously ill with kidney disease.

The Congolese Labour Party—theoretically the ruling body—is to hold its Third Extraordinary Congress later this month, and it is hoped that certain political detainees may be released in an amnesty for the occasion. The Congolese government, however, categorically denies having any political prisoners at all, and maintains that Professor Lissouba was involved in the assassination of President Nguabi in 1977.

Detailed enquiries by Amnesty International (whose charter precludes intervention in cases of political violence)

failed to find any substance in this charge—indeed, Professor Lissouba was adopted as an Amnesty International "Prisoner of the Month".

Professor Lissouba's arrest and imprisonment are almost certainly due to his political career during the 1960s. Although he had resigned the Premiership in 1966, after a disagreement with the then President, Massamba-Debat, and withdrew finally from politics in 1969, in order to devote himself to his work in cell biology, he was still, apparently, considered a focus of potential political opposition.

In 1976, when the military government was facing a general strike, Professor Lissouba was placed under house arrest for a time and deprived of his position as Professor of Cellular Biology at Brazzaville University. At the time of his arrest, he was under a restraining order forbidding him to leave the country.

Dow fights ban on 2, 4, 5-T: The Dow Chemical Company and 10 other plaintiffs are seeking an injunction to prevent the US Environmental Protection Agency enforcing its ban on the sale of the herbicides 2, 4, 5-T and Wilvex. They argue that the ban is based on a "seriously flawed study" which linked miscarriages in Oregon with herbicide spraying in nearby forests. They have asked a district court judge in Michigan, the chemical company's home state, to declare the EPA's emergency suspension orders "arbitrary and capricious", and to set them aside. The EPA has agreed to hold hearings requested by Dow and five other chemical manufacturers and users to consider lifting the emergency ban.

UKAEA responds to environmentalists' demands: The UK Atomic Energy Authority has agreed to let Friends of the Earth publish a critique of the Inhaber report on alternative energy in its magazine ATOM, subject to review by Professor F. R. Farmer, the AEA's health and safety adviser (1 March 1979). The AEA will also give FOE space to criticise Lord Rothschild's Dimpleby lecture on risk and will circulate a notice with its release of Rothschild's lecture saying that a contrary view is available.

California law on nuclear waste "unconstitutional": A federal judge in California has ruled that the state's law prohibiting the construction of nuclear power plants until a waste disposal system has been approved by the federal government is unconstitutional. The law has meant the virtual abandonment of plans for further nuclear power stations in California. Uncertainty over methods for disposing of nuclear waste has also led to similar moratoria in other states. Judge William B. Enright, however, ruled that the state law disrupted national plans for the development of nuclear energy, and that such preemption of the federal government was unconstitutional.

GMAG must cover industrial research, says the minister: Early fears that the widespread use of genetic engineering might be hazardous if organisms containing recombinant DNA were to escape "may have been mis-stated", Mrs Shirley Williams, UK Secretary of State for Education and Science told the House of Commons Select on Science and Technology last week. Nevertheless she does not think that this would justify moving "as far as NIH" in relaxing guidelines. In particular she feels that industrial research must come under GMAG's remit even though its inclusion means that some members must leave during discussions of a commercial nature. "If we said that no one could withdraw then we would have no industrial members or a lack of cooperation from industry".

Baikal railway raises environmental questions

"We are setting aside vast resources for the construction of the Baikal-Amur Mainline Railway" said Mr Kosygin, earlier this month. "Its commissioning will enable the rich natural resources of the trans-Baikal area, southern Yakutia, the Far East and Western Siberia to be more intensively exploited".

BAM—the Baikal-Amur Mainline—is due for completion in 1983. It has considerable symbolic importance to the Soviet planners. Its 3,000 km of through track (plus spur lines to major coal and ore deposits) will help to open up Siberia by providing a northern alternative to the existing Trans-Siberian route.

BAM was based on almost 13 years of surveying, before construction was begun in 1974—a survey which made extensive use of satellite photos, incidentally fulfilling Five Year Plan directives that the "exploration of near-Earth space" should be used "in the interests of the national economy".

Numerous research bodies were drawn into the planning of the project. A major role was played by the various institutes of the Siberian branch of the Soviet Academy of Sciences and the Far Eastern Science Centre. The Institute of Siberian and Far Eastern Geography has mapped the plant distribution of the BAM zone, classifying the various natural regions and determining the plant resources and the role of plants in erosion protection.

The same institute has also made a detailed survey of meteorological conditions, especially avalanches, in the

Kodar and Udokan ranges, while the Institute of Geology and Geophysics of the Siberian branch of the Academy has been working on tectonic movements. Preliminary results have been somewhat surprising. In the region of Lake Baikal, the rate of vertical movement of the crust appears to exceed that in the Caucasus, increasing northwards, so that Irkutsk is rising at 8 mm per year, and Nizhne-Angarsk (a station on BAM) at 19-20 mm.

Since the BAM zone is so highly seismic, the Institute of the Earth's Crust of the Siberian branch of the Academy developed a network of automatic seismic stations. So far, some 3,500 weak tremors have been registered and the system is shortly to be extended. Using aerial and satellite photography and computer simulation, a team from Alma-Ata are mapping sites of potential mud torrents in the future BAM industrial zone.

In addition to this seismic expertise, there have been several less expected spin-offs from BAM. One of the most interesting occurred on the section between the Baikal and Severomuisk tunnels, where the incursion of modern man turned up traces of primitive man, who, it would seem, first appeared in the area some 180,000 years ago.

Apart from problems directly connected with construction, however, the main direction of research has been ecology and conservation. From the beginning, BAM was planned with considerable respect for the environment. At times, the precautions seemed almost ludicrous, as when construction workers

were forbidden to use pesticides against the swarms of mosquitos which ruin the Siberian spring.

For the most part, though, the ecological planning was serious and well-founded. Round the northern shore of Lake Baikal, the original plan called for either a shore tunnel or else for the track to be laid along the actual shore of the lake. In the interests of conservation, however, it was finally decided to tunnel through the solid rock, to protect the lake from debris.

A vast nature reserve has been set aside in the BAM zone, including coniferous and mixed forest, mountains, rivers, lakes and alpine meadows. Fauna thus protected include wild elk, reindeer, black stork, white tailed sea-eagle, sable, brown bear, ermine and lynx. New legislation will ensure adequate crossing points for migrating animals to traverse BAM.

Planning is going forward, too, for the ecology of the future settlements of the area. Industrial complexes will be surrounded by green belts. According to Academician Brezhnev, Director of the Plant Breeding Institute of the All-Union Academy of Agricultural Sciences, "specialised farms" are to be set up along the route, which will produce fresh produce all the year round for the new towns. Sociological problems of life in remote settlements, and estimates of requirements in housing, education and recreation facilities are well under way.

However, perhaps the most unlikely spin-off from BAM is the tacit acceptance, in mass-media reports, that the seismic problems of the zone are due to plate tectonics. Until recently, Soviet geologists have been reluctant to commit themselves publicly to plates, due to the opposition of the prestigious Academician Belousov. Recent TASS releases, however, accept plate tectonics as an accepted feature of the BAM zone. Indeed, TASS reported last January that, owing to plate movements, by the end of the century, BAM will be some 50 cm longer than planned.

Vera Rich

The Baikal-Amur railway: route to the wealth of Siberia

Multiple aimpoints not the answer

The Carter administration is expected to decide next month which of a variety of possible basing modes it will adopt for the deployment of its new generation of intercontinental missiles, the MX. Richard Garwin here discusses how the alternatives relate to the current agreement on strategic arms limitation being negotiated with the USSR.

WIDELY heard around Washington these days is the acronym MAP, for Multiple Aimpoint System (also known as "MPS", for Multiple Protective Shelter). MAP has emerged as this year's leading contender to the endemic problem of the vulnerability of US intercontinental Minuteman missiles. But among the difficulties which MAP poses could be its impact on the structure and progress of SALT, the Strategic Arms Limitation Talks.

At present the United States deploys 1,000 Minuteman missiles in silos; a little over half contain three re-entry vehicles (RVs) per missile, the remainder only one. Minuteman silos are concentrated into six wings at separate locations in the United States. This concentration is in itself a weakness of the Minuteman force, for unless the United States chose to launch a planned strike it would be possible for the Soviet Union to create for a limited period an environment in which there was no point in launching missiles. Around one megaton detonated every minute above the atmosphere in the vicinity of each Minuteman wing would reliably 'pin-down' the missiles, which are fragile during the boost phase.

Such an attack, started perhaps with submarine launched missiles of short flight time and continued with land-based missiles, could not continue indefinitely. At some stage a direct attack would have to be made on the silos themselves. It is widely recognised now that Minuteman is not vulnerable to a short-duration attack unless enemy RVs are so accurate that no more than two (and preferably one) need be used against each silo. Even the low airburst required to produce sufficient overpressures on the ground to destroy a Minuteman silo throws a large amount of debris into the air, and causes problems with the penetration of a second RV to the target region.

The current interest in vulnerability arises from the improved accuracy demonstrated by Soviet missile tests. If the Soviet Union indeed deploys

2,600 or so RVs against Minuteman, with no systematic errors in targeting, and if the operational aspects of timing, command and control can be resolved, as well as the problem of retargeting backup missiles to replace those which have failed to emerge from the silo or have failed in boost, then the Soviet Union should be able to destroy a large fraction of the Minuteman force at some time in the 1980s—supposing Minuteman is not launched under attack or on warning of attack. Why it would want to spend 2,600 megaton-range RVs to destroy 2,000 submegaton-range RVs is a question which has not been given a compelling answer. The Soviet Union would reduce its own RV numbers (already below those of the US) by a larger fraction than would the United States, and would have expended three to four times as many megatons as it had destroyed. The US would still possess a large fraction of its 4,960 Poseidon warheads on nuclear submarines.

If the Soviet Union should choose to do this, however, MAP is an eminently rational proposal to counter Minuteman vulnerability. Grant the Soviet Union perfect reliability of its missiles and re-entry vehicles, essentially perfect accuracy and perfect knowledge of the locations of our land-based missiles, and the desire to destroy the US inter-continental ballistic missile force (ICBM). Grant that the US ICBMs would remain in their silos until after an attack, rather than be launched under attack or on warning. Then in principle one could preserve a substantial fraction of an ICBM force by siting individual missiles deceptively in a number of 'aimpoints' substantially larger than the number of RVs which the Soviet Union might bring to bear in an attack. A figure of 5,000–6,000 aimpoints has been discussed, and this could preserve more than half the US ICBMs against a Soviet force of 3,000 re-entry vehicles.

The number of US missiles actually secreted can be chosen to satisfy US force requirements, as can the size of the missile. One might imagine 1,000 single-RV missiles, each with an RV comparable with that on Minuteman III, or alternatively, a force of 200 large missiles in the same 6,000 shelters, each with 10 or 11 RVs of the same type. The choice of missile is strongly influenced by SALT considerations. The keystone of SALT II is equal numerical limits on ICBMs, and particularly on those containing multiple re-entry vehicles, and so the possibility of doing MAP under SALT leads one to consider very large mis-

siles in order to have the largest throw-weight possible.

A typical breakdown of costs would be \$5 billion for missile R&D; \$3 billion for missile procurement (200 of 11 RV each); and \$20 billion for construction and maintenance of aimpoints. Because the cost of MAP is very largely in aimpoints, there is every incentive to reduce their cost—although that conflicts with the desire to have a large missile. On the other hand, a MAP-deployed ICBM force could be expanded greatly at little extra cost. With missile procurement a small fraction of total cost, there would be substantial interest in tripling or quadrupling the total missile throw-weight after deployment. This would be hard to resist unless constrained either by policy or by SALT.

Invulnerability of MAP is only guaranteed if the Soviet RVs remain fewer than the number which MAP is designed to counter. Even with achievable accuracies and reliabilities, a Soviet force of two RVs per MAP shelter could destroy a very large fraction of missiles, and the projection of such capabilities might lead to an early Soviet conclusion that MAP will be as vulnerable against the evolving Soviet force as is Minuteman now.

The MAP system would be even more vulnerable if the Soviet Union could learn which MAP shelters contained real missiles. Present discussions largely focus on shelters which contain either real missiles or decoys which look very realistic. Operational personnel probably must themselves be kept in ignorance of which shelters contain real missiles. When a missile is returned for service, for instance, its 29 decoys would also be returned.

The real problems with MAP are twofold. First, I believe that by the time MAP can be fully deployed, about ten years from now, the Soviet Union will readily have accuracies on the order of 100 m, allowing RV yields to be as low as 50 kilotons for effective destruction of MAP shelters. Such accuracy would come about not simply by improvement of inertial guidance systems, but also by capitalising on the availability of satellites (or ground-based radio transmitters) which will provide 10 m positional accuracy in three dimensions world-wide every 0.1 seconds. Thus it would be very difficult to argue that the Soviet Union, bent upon imperilling the land-based ICBM force, could not threaten MAP at modest cost. Further, the Soviet Union could readily stay ahead of the deployment of additional aimpoints if these aimpoints were sufficiently costly to

Underground missile sites are always vulnerable; in-shore submarines could be the answer

accommodate large missiles—probably around \$2 million per aim-point.

A second problem concerns leaving room for MAP within SALT (as demanded by Chairman of the Joint Chiefs General David Jones and by Secretary of Defense Harold Brown), for it would permit the Soviet Union to do likewise. Some may worry about the number of missiles the Soviet Union has deployed in its (hypothetical) MAP fields; I think the problem is a different one. The Soviet Union could manufacture a large number of MAP missiles, keeping them in store until it wanted to abrogate SALT. It could then deploy them within weeks into hardened MAP shelters already in existence and provided with good command, control, and communications. If a durable, accurate, commandable ICBM force does indeed convey a political advantage—as many critics of SALT assert, and hardly anyone is willing to challenge—the Soviet Union could in this way have seized an advantage unavailable at present.

For these reasons, I personally believe that we should not allow in SALT II the possibility of deployment of MAP, and that the US should not go ahead with MAP under SALT.

One basing mode for ICBMs free of pin-down constraints, and not vulnerable to improved accuracy and further fractionation of the throw-weight of Soviet ICBMs, would be to carry 6,000-mile range missiles horizontally outside the hull of many small submarines deployed close to US shores. Each submarine might weigh 350 tons and carry some 350 tons of missiles. At least 400,000 square miles is available within 200-300 miles of US shores,

far too large an area to be barraged by Soviet nuclear weapons. The proximity to the shore allows efficient use of submarine time even if the maximum speed were only 5 knots, for which a 30-kW propulsion plant would serve.

Available in the nearer term is the air-launched ICBM. Large military cargo aircraft would be stationed routinely, one or two at a time, at sparsely-equipped bases in the Central US. Each would contain one or more modern ICBMs which are launched by being dragged out of the aircraft by parachute, and fired within seconds.

Survival of the aircraft would be assured by rapid takeoff in response to indications by infrared warning satellites of attack. The aircraft could also be launched if this warning system were disrupted or destroyed, flying to one of a large number of dispersed military or civilian bases within the United States. Such a system could be made more secure if it were based on advanced short-take-off aircraft.

Because the missile would be launched from aircraft at altitude and speed, a substantial increase in number of RVs would be available in comparison with surface or submarine launch. Compared to conventional bombers, the military cargo aircraft would be much simpler and would have a higher readiness rate, thereby making the system cheaper for a given number of alert missiles. Unlike MAP, the system would preserve a very large fraction of the deployed missiles against the assumed threat. In the past, such concepts have encountered cost difficulties; it remains to be seen whether the management techniques used by the US Air Force in holding down

operational cost for silo-based systems can be applied to a new-generation ICBM and its aircraft.

Finally, because Minuteman silos are so numerous and considerably 'harder' than an RV they could in fact be defended at an affordable cost. This is not true of unique targets such as command centres, nor targets such as cities against which dozens of nuclear warheads could be used. Effective nuclear defence of Minuteman silos could be achieved by burying a nuclear explosive about 1 km north of each silo and detonating it under the control of an upward-looking mini-radar a few km further north. A non-nuclear defence which is receiving some attention uses similar mini-radars north of each silo to predict the arrival time and point of each RV at an imaginary screen some 1 km north of a Minuteman silo. At this point the RV would be met by a flight of 10,000-40,000 mini-rockets (about 500 g each) flying at a speed of 1,000 m/sec from a launching silo near the Minuteman silo. Because the radars look at the threat RVs from the side and not from the nose, and particularly because they see them at 2 km distance rather than 100-1,000 km range, they can be very small and cheap. Although they are more vulnerable to attack than a Minuteman silo when operating, the radars can be made effectively immune by the use of additional radars in mini-silos to be put into service after the operating radars are destroyed. Such a system might serve to prolong the life of Minuteman silos during the awkward period from 1982, when the Defence Department assesses vulnerability to be likely, to the completion of full-scale deployment of some new ICBM basing mode in 1988.

In conclusion, I believe that MAP is a non-starter. It is far too expensive, far too late in remedying Minuteman vulnerability (if such be important), essentially incompatible with SALT, and burdened with environmental problems. While the possibility of defending existing Minuteman silos suffers from lack of appeal to advanced technologists, it deserves more and urgent attention. In my opinion, the basing of a new generation of encapsulated ICBMs on near-ocean submersibles is also very attractive, and it may have some appeal in the modernisation of the strategic nuclear force of the United Kingdom. The more familiar concept of air launched ICBMs, though perhaps more expensive than the mini-subs, may be available sooner as an effective counter to Minuteman vulnerability.

correspondence

Smallpox research at Birmingham

SIR,—We took note of your editorial (11 January, page 75) concerning Professor Shooter's report and related aspects of the smallpox case in Birmingham.

It may seem surprising to your readership that, to date, various statements and opinions concerning this report have gone unchallenged by Professor Bedson's colleagues. We, who are members of the Department of Medical Microbiology, should like to record that this does not imply acquiescence or agreement with public statements concerning the report nor indeed, with the content, interpretation and conclusions of the report. The Shooter report is not yet public and there is pending a prosecution from the Health and Safety Executive; on this account, it seemed improper to make public comment.

We think, however, that in certain areas of your editorial the reader is entitled to some factual information. For example, with respect to Dr Mark Darlow's statement that many academics still believe that "what was good enough for Pasteur is good enough for me", we feel that most academics would wish to know which of their fellows supported this contention; and later, with respect to Dr Darlow's comment: "Bedson knew he was backing a lame horse and that it would stumble sooner or later. It stumbled sooner," we should like to enquire what evidence led Dr Darlow to this conclusion and, further, was his conclusion based on personal knowledge of Professor Bedson and his department or on his own interpretation of the report?

It does not seem to accord with the opinion of grant-giving bodies who were supporting the work, nor with that of his academic colleagues in the Department of Medical Microbiology. One minor point—your editorial properly refers to Dr Darlow by his correct professional designation; we feel disappointed that Dr Darlow did not see fit to accord the late Professor Bedson a similar courtesy.

Finally, your extensive editorial, which we felt to be a very reasonable assessment of the Shooter report is, *de facto*, based only on the findings of the report and must, of necessity, depend on the assumption that the report is a correct and reasonable account. In our opinion, it is not a correct and reasonable account, and quite simply is unfair to Professor Bedson and his professional reputation. We hope for the courtesy of your columns at a later date (when the Shooter report is public) to communicate to the academic readership our personal reservations and criticisms.

Yours faithfully,

G. R. B. SKINNER

Undergraduates more numerate?

SIR,—Joseph Schwartz' interesting article on numeracy in Britain (1 February, page 344) gives obvious cause for thought as to the basis on which one can make any statement concerning supposed changes in numeracy over the years. So far as university entrants are concerned one hears many subjective views expressed, mostly of a pessimistic kind, but seldom are any hard facts adduced in support of these views. In the absence of any long-term research study having been carried out over the last decade or two it is hard to reach any conclusions that would satisfy the stringent requirements of a research publication, but our own experiences with biological sciences students at Leicester may provide a pointer, at least so far as one identifiable group of 18-year-olds is concerned.

In common with many other schools of biological sciences we find it necessary to teach a limited degree of basic algebra and statistics to our entrants, most particularly to those (over half) who have not read A-level mathematics. We have taught such a course to our first years since the inception of the school in 1968 and at least since 1971 the format, content and method of assessment of the course (mostly by computer marked multiple choice tests with questions drawn from a largely unvarying data bank) have remained unchanged. The average A-level attainment of our entrants, and the proportion having A-level maths have also not changed significantly during this period.

Until some three years ago one could safely predict that some 10–15% of our entrants would be almost entirely unable to cope with even the simple course which we give. At the other end, the numbers gaining a very high mark would never exceed 20%, and was often much lower. Each of the last three years, however, has seen a clear improvement over any previous year, either in the numbers failing, the numbers gaining a distinction, or both.

Other than an improvement effected three years ago in the physical arrangements for our problem classes (which could be significant) those of us who lecture in this course are not aware of any change in our teaching technique in the last three years, and indeed with the rise in the proportion of entrants who have taken "modern maths" at school a certain communication problem is beginning to be evident.

These observations clearly cannot be taken as definitive evidence for a rise in numeracy amongst our entrants, even though my subjective judgement would be that our current entrants are much less afraid of numerical work than their predecessors of, say, seven or eight years ago.

They most certainly, however, do not lend any credence to the notion of a decline in numeracy in the group concerned, and in areas such as computing and numerical biology in which we give

rather detailed courses at Leicester, we have good cause for satisfaction with the level of interest and attainment found. It would be interesting to know if other institutions which have admitted students over a number of years and have assessed their numeracy in some way have had similar experiences.

Yours faithfully,

A. J. ROWE

University of Leicester, UK

Scientists should press for Freedom of Information

SIR,—As a public member of the all-party Parliamentary Freedom of Information Campaign (FOIC), I should like to draw the attention of the scientific community to the important private member's bill of Mr Clement Freud MP, called an Official Information Bill, which has been given an unopposed second reading (*Hansard*, Vol 960, No 38, 19 January), and is now in its committee stage.

The main purpose of this measure is to repeal the notorious "catch all" Section 2 of the discredited Official Secrets Act of 1911, and to replace it by a form of Freedom of Information legislation. This latter is broadly in accordance with the obligation of the United Kingdom as a signatory to the European Convention on Human Rights and Fundamental Freedoms, and with especial reference to Article 10 (freedom of expression) of the Convention. Thus, the Council of Europe (Report No 4195) calls upon "the governments of member states which have not yet done so, to introduce a system of freedom of information, ie access to government files, comprising the right to seek and receive information from government agencies and departments, the right to inspect and correct personal files, the right to privacy and the right to rapid action before the courts in these matters."

On behalf of the FOIC, I therefore urge all members of the scientific community to write to their MPs to support the Official Information Bill during its next stages in Parliament; and to make representations through their unions to similar effect. (Freedom of Information legislation is official TUC policy.)

And finally, I appeal to those members of the scientific community living in countries which have already introduced Freedom of Information into statute law, to impress upon their British colleagues, in their various contacts with them, the importance of such legislation both for the advancement of science (and the public interest) in the United Kingdom and for the broader aims of effective international cooperation.

Yours faithfully,

STANLEY ALDERSON

Cambridge, UK.

news and views

LEAD is an extremely useful metal and men have mined and smelted it for over 8,000 years. The enormous demand for the metal in classical times produced widespread and generally fatal plumbism among the slaves and prisoners who usually mined it. Occupational plumbism was for centuries a serious menace among lead workers, potters and in lead pigment mills (see Dickens 'A Star in the East' in *The Uncommercial Traveller*); however the general public was not exempt from the ravages of this disease. Widespread and frequently fatal colic epidemics, usually caused by lead-adulterated wines ravaged many parts of Europe until the 19th century (see *TIBS* 2, 147; 1977).

Environmental lead poisoning of comparable severity is fortunately rare today (but see 'Thai village finds tragedy on a road paved with lead [slag]', *New York Times*, July 5; 1977), but the levels of lead in the environment as well as in the bodies of inhabitants of industrial countries have

Living with lead

from Josef Eisinger

been rising along with the exponential growth of lead production and are now one or more orders of magnitude greater than the 'natural' levels. This has evoked considerable concern among the public as well as governmental health authorities grappling with the task of defining safe limits for environmental lead exposure.

The most important biochemical interactions of inorganic lead are characterised by the ions' propensity for binding to sulphhydryl groups which leads to the inhibition of many different enzyme systems. As a result the early symptoms of chronic lead intoxication are variable and nonspecific and the

problem of relating exposure to disease (for example, effects on the nervous system) is a difficult one and is, because of its economic ramifications, often controversial.

A recent report (*Investigations into lead from motor vehicles*, Chamberlain *et al.*, Harwell, HMSO; 1978) illustrates one approach to improving our understanding. It presents the results of a painstaking experimental study of the pathways by which lead enters and leaves our bodies and what is the size and fate of the fraction which stays behind.

Since the study, which employs the tracer ^{203}Pb ($T_{1/2}=52\text{ h}$) as well as stable lead, is primarily concerned with emission from motor vehicles it includes ambient measurements of the concentrations and size distributions of lead aerosols near roadways. These are found to depend upon driving and weather conditions, with air lead levels near motorways ranging up to $10\text{ }\mu\text{g m}^{-3}$, about the same as in the vicinity of lead smelters. Air levels in busy London sites are broadly speaking about half of this value and inside a car the levels are only slightly lower. From the data given and some reasonable assumptions the amount of lead emitted along a road carrying an average of 1,000 cars per hour is $100\text{ g m}^{-1}\text{ d}^{-1}$, some 10% of which is deposited within 100 m of the road.

When such lead laden air is inhaled, approximately a third is deposited in the lung although this fraction is considerably higher for very small aerosol particles ($<0.05\text{ }\mu\text{m}$) and there appears to be a significant variation among the subjects who participated in these experiments. Clearance rates from the lung follow complex kinetics, depend on particle size and chemical composition and again show individual variability. About a day after a person is injected with or inhales ^{203}Pb , his blood lead level reaches a maximum and the total amount in his blood is approximately half of the dose given.

The efficiency with which lead compounds are taken up from the gut is also found to vary considerably from subject to subject (for example 2–26% for PbS) and depends on the chemical composition, with even nominally insoluble compounds (for example PbCrO_4) being taken up quite efficiently, presumably because of the high stomach acidity. A full stomach is found to offer a measure of protection:

This woodprint from Agricola's *De re metallica* (Basle, 1556) shows the smelter foreman eating from a tub of butter which, the caption explains, is a specific remedy against the poisonous lead fumes issuing from the smelter behind him.

A 12-hour fast increased the efficiency with which PbCl_2 is taken up from 7 to 45%. This appears to bear out the traditional advice offered to lead workers and potters by the earliest miners' physicians, to eat lots of fatty foods and soups (Stockhausen *Libellus de lithargyrii* . . . Goslar, 1656, see figure).

Chamberlain *et al.* (*op. cit.*) perform a great service by presenting a synthesis of their results and those of other investigators in the field. This should be useful in constructing kinetic models for the lead transport within the body. The factor relating blood levels (in $\mu\text{g dl}^{-1}$) to ambient air levels (in $\mu\text{g m}^{-3}$) for instance, is found to range from 0.5 to 2, depending on the investigator and/or the methodology employed.

The most significant conclusion from the point of view of environmental policy may be that at $1 \mu\text{g m}^{-3}$, the average air level in British cities, the ratio of air lead to other lead intake is low, between 8 and 20%, and is in substantial agreement with the conclusion of another recent study (*Lead pollution in Birmingham*, HMSO, 1978). The importance of local conditions can be seen from the finding that the mean lead level in the blood of mothers and children in North Wales is doubled if their houses have lead, as opposed to copper piping (Elwood *et al.* *Lancet* **i**, 1363; 1978). This suggests that the greatest lead intake among the general population in Britain is caused by lead piping in soft-water areas.

A somewhat different approach to the problem of gauging the severity of environmental lead disease makes use of biological indicators of lead toxicity. While the blood lead level has been used traditionally for this purpose it suffers from serious drawbacks in that such assays are slow, expensive, require skilled personnel, have poor reproducibility and are prone to contamination errors. In view of the complex and variable kinetics of lead transport with-

in the body the blood level is moreover an indicator of uncertain validity for long term lead exposure. While elevated porphyrin levels have long been known to be associated with lead disease (Watson *et al. Pediatrics* **12**, 40; 1958) the zinc protoporphyrin (ZPP) level in blood has been demonstrated recently to be a superior indicator to blood lead, in that it was found to correlate better with the signs and symptoms of chronic lead disease and has, as will be seen below, numerous practical advantages as well. (Eisinger *et al. J. Env. Path. Tox.* **1**, 897; 1978; Grandjean *et al. Scand. J. clin. Lab. Invest.* **38**, 669; 1978).

The enzyme ferrochelatase inserts iron into protoporphyrin IX to form haem and is inhibited by lead ions at the site of erythropoiesis. When this occurs (or if there is a shortage of the substrate Fe^{2+} as in iron deficiency anaemia) zinc ions, which are available in the bone marrow are substituted for iron to form ZPP which is then incorporated in the globin (Lamola *et al. Science* **186**, 936; 1974). The resulting impairment of the blood's oxygen carrying ability is negligible since the haemoglobin of even seriously lead poisoned persons contains less than 1% of ZPP-globin. What makes this assay for lead toxicity so useful is that (1) ZPP levels in blood can be measured fluorometrically since ZPP fluoresces while the haem does not, and (2) ZPP-globin once formed, remains in the erythrocyte for the life time of the cell (~ 120 d) so that ZPP level in blood is an indicator with a 4-month integration time (Lamola *et al. J. Lab. clin. Med.* **56**, 1528; 1975). This is particularly important where exposure is chronic but intermittent.

In the US the ZPP assay has been recommended for the screening of children for lead exposure by the Center for Disease Control, with the test's response to iron deficiency anaemia being considered an additional advan-

tage. Recently the US Occupational Safety and Health Administration while retaining standard limits for environmental and blood lead levels, recommended ZPP assays for the medical surveillance of lead exposed workers (*Fed. Reg.* **43**, No. 220; 1978).

ZPP levels in blood have a considerable dynamic range. The blood of city and country dwellers typically register 50 and $20 \mu\text{g dl}^{-1}$ respectively while that of lead workers can range up to $1,000 \mu\text{g dl}^{-1}$ (Lilis *et al. Environ. Res.* **14**, 255; 1977). Central nervous system dysfunction, probably the most serious but elusive aspect of lead disease, has been shown to be significantly correlated with the blood ZPP levels (Valciukas *et al. Science* **201**, 465; 1978).

The ZPP assay is not only a meaningful indicator of lead disease but a particularly convenient one, because of the development of a portable instrument. This dedicated front face fluorometer, called a haematofluorometer, requires only a drop of blood, generally obtained by finger puncture (Blumberg *et al. J. Lab. clin. Med.* **89**, 712; 1977). The blood is smeared on a glass cover slip which is inserted in the instrument, and a digital display gives the ZPP level in convenient units within seconds. Since haematofluorometers have become commercially available, ZPP levels can now be measured quickly, accurately and at a small fraction of the cost of a blood lead determination. One may hope that ZPP assays will be useful not only for the screening of potentially exposed persons, but that they will make feasible large scale epidemiological studies of the general population to improve our understanding of the relationship between lead exposure and disease. $\square$

A hundred years ago

We are greatly disappointed and much surprised to learn that the application of the Scottish Meteorological Society for assistance to establish an observatory on Ben Nevis has been rejected both by the Meteorological Council, with its yearly 15,000*l.*, and the Government Grant Committee, with its 5,000*l.* The former had other matters to attend to, the latter handed the application over to the Council of the Royal Society, labelled "highly commendable." We have recently shown our readers with what heartiness and cosmopolitanism such nationally beneficial undertakings are managed in France; yet in this disgracefully wealthy country, with 15,000*l.* a year expressly devoted to meteorology, a plan of promoting meteorological research that would lead to results of the highest consequence must collapse for want of a paltry 500*l.* to start it. It would be a

shame if so really national an enterprise were to depend entirely on private subscription.

From *Nature* **19**, 13 March, 445; 1879.

A REMARKABLE phenomenon is reported from Neufchatel. On February 10 the Lake of Neufchatel suddenly assumed a motion like the sea with its tides, only with the difference that the rise and fall of the water succeeded each other in much shorter intervals. The phenomenon began at noon and lasted until 2 p.m. Boys who were playing on the shore were so suddenly surprised by the rising lake that they were up to their knees in water before they had time to escape. In the evenings there was a violent thunderstorm, which also visited Berne at the same time.

From *Nature* **19**, 13 March, 446; 1879.

INTERESTING correspondence has appeared in the British Guiana *Royal Gazette*, we learn from the *Colonies and*

India, relative to the qualities assigned to the fruit of the papau-tree. It has been recently asserted, in an article in the *Pharmaceutical Journal*, "that the most interesting property attributed to it is the power of its juice to render bad flesh tender." Mr. Monro, of Georgetown, furnishes certain facts which he says are commonly known to the natives of British Guiana relative to this fruit. A horse tied near one of these trees rapidly loses health, and a stud horse becomes useless. Any pressure on the body of the animal leaves an inelastic indentation. The sap of the tree will soften steel, and before the process of tempering was known in the Colony, the blacksmiths used to drive their brittle chisels and plane vices into the wood, leaving them there for a day or two; and tough meat wrapped in the leaf for only a few minutes becomes tender.

Unified field theory: dream becoming reality?

from F. E. Close

EINSTEIN spent the latter part of his life attempting to find one formula that would explain both the gravitational and the electromagnetic field. Pauli believed this to be impossible stating "what God hath put asunder, no man shall ever join".

Einstein failed in his quest but recent theoretical developments in high energy physics, combined with sophisticated experiments, suggest that we may be at the threshold of a profound unification of electromagnetism with the weak force of radioactivity and also the strong nuclear force. This will leave gravity as the final link in a grand synthesis.

Thus the centenary of Einstein's birth is an appropriate moment to outline why the high energy physics community is so optimistic that such a grand scheme may be at hand, even though gravity itself is not yet included.

Electromagnetic and weak interactions

The electromagnetic force has been well understood for 30 years. It is mathematically described by quantum electrodynamics, QED, the theory of the interaction of charged particles with photons (the quanta of the electromagnetic field).

As long ago as 1934 Fermi had recognised some similarities between the weak β -decay of the neutron and electromagnetic phenomena. This led him to propose a model for the weak interactions. This model was perfectly adequate as a description of laboratory phenomena but was found to contain internal inconsistencies if applied to extremely high energies. In 1957 Schwinger showed that if there existed electrically charged W bosons then the deficiencies of the Fermi model could be made less serious.

These W bosons of the weak interactions have a role analogous to the photon in QED. They are predicted to be about 70 GeV in mass (the proton is but 1 GeV mass) and it will be another couple of years before machines will be developed that can produce them.

In the 1960s Glashow, Salam and Ward and also Weinberg were instrumental in using this idea to create a model which unified QED and the weak interaction. If the W bosons had been massless, like the photon, then 'weak' interactions and electromagnetic interactions would have had essentially the same strength and been manifestly recognised as being 'the same'. The fact that $W^\pm$ are so massive is the

reason why interactions with W bosons are so much weaker than those with photons and makes electromagnetism and the weak interaction seem to be different.

In 1970 't Hooft showed that this model was completely self consistent, violated no sacred principles and was thereby a candidate theory unifying the weak and electromagnetic interactions. Accumulating data during the past 5 years, and in particular in 1978 (see *News and Views* 264, 505; 273, 99; 274, 11; 275, 267) now give solid evidence showing that this theory is very near the truth, and could even be completely correct.

This theory is known as quantum flavour-dynamics, QFD, and contains QED within it. The unified electromagnetic and weak force is often referred to as the 'electroweak' force.

QCD: a theory of strong interactions

Particles like the proton which feel the strong nuclear force appear to be complicated systems of more fundamental particles called quarks. Quarks have electrical charge and flavour and so partake in interactions with photons and W bosons, that is, the electroweak interaction. They also appear to carry a further kind of charge known as a colour charge. It is hypothesised that there exist coloured gluons, analogous to the photon of QED, which couple to this colour charge and hence generate the strong interaction. The resulting theory is called quantum chromodynamics, QCD, and has many similarities to QED. This theory is still very young and its richness is only gradually being understood. Quantitative definitive tests are slowly being found and the first data that are being accumulated appear to be in excellent accord with the predictions (see *News and Views* 277, 349; 1979).

Grand unification

QED involves interaction of electrical charge with photons; QFD involves interaction of flavour with W bosons and QCD involves interaction of colour charge with gluons.

This qualitative similarity between the three theories is manifested mathematically, the three differing only in internal symmetry properties which are described by group theory. QED is a $U(1)$ field theory containing one 'gauge boson'—the photon. An $SU(N)$ 'non-Abelian' field theory has N^2-1 gauge bosons; hence three ($W^+W^-W^0$) for the $SU(2)$ QFD and eight gluons for the $SU(3)$ QCD (see for example *News and Views* 277, 349).

The idea behind grand unification is to find a super group G which contains $U(1) \times SU(2) \times SU(3)$ (QED, QFD and QCD). The simplest example for G is the group $SU(5)$. The above (N^2-1) rule shows that there will be 24 gauge bosons. Twelve of them will be the photon, three W bosons and eight gluons. A further dozen are thereby predicted.

The $SU(5)$ supergroup accommodates a pair of leptons (for example e^- and ν) partnered by a pair of quarks (u and d). The quarks necessarily have colour while leptons do not. These features are all in accord with experience. This pairing of a lepton doublet with a quark doublet has been recognised for some time and the set is often referred to as the 'first generation of elementary particles' (see *News and Views* 271, 406; 1978). Nature appears to have made xerox copies: a second generation ($\mu^- \nu'$ and cs) and possibly a third generation ($\tau^- \nu''$ and $t(?)b$). This is acceptable in $SU(5)$, if somewhat unnatural.

The twelve new gauge bosons of $SU(5)$ can cause quarks to transmute into leptons. This will make the proton unstable (see below) and may provide a test of this idea. Indeed this prediction of proton instability is not unique to the $SU(5)$ idea and occurs in other candidate schemes where G is the group $SO(10)$ or the exceptional group E_6 . These different groups make different predictions for the menu of quark and lepton flavours that await discovery at the new accelerators.

Asymptotic freedom and grand unification mass

The possibility that we may be able to invent a sensible grand unification scheme has come from the discovery of the electroweak unification and also the possible discovery of the laws governing the strong interaction (QCD). Of particular significance in the latter case has been the discovery of the property of 'asymptotic freedom'. This appears pivotal to the grand unification idea.

The strength of the strong interaction at low energies is much greater than the electroweak interaction. The quark-gluon coupling decreases in strength as energy or mass increases until asymptotically it tends to zero (this is 'asymptotic freedom'). There will therefore exist an energy scale where the 'strong' interactions are no longer strong, but have comparable strength to the electroweak. At such an energy 'unification' can have a well defined meaning.

This energy scale can be calculated, and turns out to be about 10^{19} GeV, and so in a realm where gravity may also begin to be important. In the original heat of the big bang such energies may have been common and a true unity may have existed. As the Universe cooled so the different interaction strengths froze out giving the strong, electromagnetic and weak interactions of the present day.

The original symmetry of the hot Universe has gone. The heat generated in high energy accelerators has managed to give a glimpse of nature soon after the big bang and reveal hints of that long lost unity. As energies are increased so one reaches nearer to that original symmetry. Therein is the aesthetic beauty of particle physics and the grand unification ideal.

Progress so far

At present, high energy physicists are concentrating on deepening their understanding of QCD and of trying to find the correct 'super group' that will enable it to be unified with the electroweak interactions.

The simplest candidate for this unifying group is SU(5), proposed by Georgi and Glashow (*Phys. Rev. Lett.* **32**, 438; 1975) and investigated in some detail by Ellis and collaborators at CERN, Geneva. A natural consequence of such a grand unification is that quarks (which experience QCD) and leptons (which only experience the electroweak force) are related. For example, if Nature contained a charged lepton of mass 10^{15} GeV (the 'grand unification mass' where all interactions have the same strength) then it is predicted that there would also exist a quark of charge $-\frac{1}{3}$ at that same mass. In practice the Universe is very cold, and particles have masses of order 1 GeV rather than 10^{15} GeV. Ellis and co-workers showed that as the lepton or quark mass comes down from 10^{15} GeV to 1 GeV, so the quark to lepton mass ratio increases. As an example consider the following.

The ratio of strange quark to muon mass is known to be about five (0.5 and 0.1 GeV respectively). After the discovery of the τ lepton in 1975 one necessarily predicted the existence of a 'bottom' quark in the SU(5) framework. The τ is about 2 GeV in mass, hence 'nearer' to 10^{15} GeV than the 0.1 GeV muon, with the consequence that the ratio of bottom quark to τ mass will be nearer to unity than was the ratio of strange quark to muon. Ellis *et al.* calculated this and predicted a mass of about 5 GeV for the bottom quark (about twice that of the τ lepton). The lightest meson built from a bottom quark (b) and its antiquark ($\bar{b}$) would therefore be expected at about

10 GeV. The discovery of Y at 9.46 GeV, made from $b\bar{b}$ (see *News and Views* **275**, 267; 1978) is in remarkable accord with this prediction.

Another interesting feature of grand unified theories is that the intimate relationship between quarks and leptons implies that quarks can transmute into leptons, albeit very rarely. A consequence of this is that the proton, which is made from three quarks, will not be stable; there is a probability that it will decay into three leptons. Estimates for the lifetime of the proton vary but it could be as 'short' as 10^{33} years.

As the Universe itself is only of order 10^{10} years old, this prediction may seem rather esoteric. However, Avogadro's number enables one to study vast numbers of protons and experimentally a lower limit of about 10^{30} years has been obtained for the proton's lifetime (Reines *et al.* *Phys. Rev. Lett.* **34**, 493; 1974). Improvement of this is feasible and so it is possible that tests of some of these ideas may be forthcoming. Several authors have recently pointed out that proton instability could be an important ingredient in quantitatively understanding the observed excess of matter over antimatter in the Universe.

Some byproducts of grand unification ideas may soon be clarified at the new high energy electron-positron collider PETRA at Hamburg. In the SU(5) and SO(10) super group schemes it is predicted that a 'top' quark must exist, charge $\frac{2}{3}$ of the proton charge, to complete the symmetry of leptons and quarks. In the scheme based on the exceptional group E_6 , however, it is predicted that you cannot have such a quark but that instead a quark with charge $-\frac{1}{3}$ will exist. Hence a search for this (sixth flavour) quark promises significant consequences for theory.

Whichever particular scheme for superunification you buy, you find the prediction of a sixth flavour of quark. Mass estimates vary somewhat but about 20 GeV seems popular. This is tantalisingly close to the maximum energy that PETRA and its Californian counterpart PEP can attain.

In addition, the quantitative successes of grand unification (such as the prediction of the b quark mass) seem to require that no more than six or eight flavours of quark and of leptons can exist. Therefore it is possible that the next generation of accelerators will reveal the end of lepton-quark spectroscopy.

If QCD can be confirmed as the correct theory of the strong interaction (see *News and Views* **277**, 349; 1979) then it seems that we will indeed have all the ingredients to hand to build a successful grand unified theory.

The menu of quark and lepton flavours and the profound similarity (and subtle differences) between quarks and leptons and also their relative masses seem already becoming more clearly understood. It seems possible that a successful grand unification might also explain the various dimensionless parameters that pervade our Universe, like α the fine structure constant, the magnitude of the Cabibbo mixing angle and the weak-electromagnetic (Weinberg) mixing angle. The possibility that the proton is not stable is also an amusing consequence.

At the centenary of Einstein's birth, this seems to be the direction in which high energy theory is moving. However, the role of gravity and its incorporation in ultimate unification, Einstein's great unsolved problem, is still unclear. Now that superunification energies approaching the Planck mass are being discussed, it seems probable that we are approaching a point where ideas in gravity and high energy physics will have to fuse if we wish to approach a full understanding of how the present cool unsymmetrical Universe froze out from the big bang. $\square$

High level nuclear waste isolation: borosilicate glass versus crystals

from G. de Marsily

IN a paper in this issue of *Nature* (page 219) Ringwood *et al.* advocate the use of an artificial crystalline material in which to immobilise the solid waste arising from the reprocessing of nuclear reactor fuel rods. He proposes to incorporate solid wastes in an artificial rock ('SYNROC') composed essentially of three minerals: hollandite, perovskite and zirconolite. According to Ringwood, up to 10% of waste could be incorporated into SYNROC; this material would be produced by hot-pressing the waste and ingredients at 1,200–1,300 °C, thus obtaining crystallisation, at a reasonable cost. This solution is clearly a serious potential competitor to the more usual glassification concept, which has been studied for more than 10 years, mainly in the UK and France, and is at present in operation in France at Marcoule.

As a geologist, I am concerned with

the leachability and stability of the waste in a geological formation, which will form the final barrier between the waste and our environment. From this viewpoint what are the differences between SYNROC and glass.

In their original form, the wastes produced by the reprocessing plants are liquid. Early projects suggested that this liquid be injected directly into the ground (either into a deep permeable layer, with immobile fluids, or into a cavity which would subsequently melt, due to the heat produced by the waste). Such projects have been disregarded, the radioactive elements being too readily available for transport by the ever present groundwater.

Incorporation of the calcined waste into a solid matrix then began to be considered. Many materials have been proposed, including glass, ceramic, cermets, metals, mica, feldspar, synthetic uraninite or thoriumite, and now SYNROC. So far glass has probably received most attention and given the best results. The leachability of glass depends on at least three distinct mechanisms: (1) dissolution of the borosilicate glass matrix in the water (in a salt environment, the solubility of silica increases, so that the thermally-driven fluid inclusions in the salt might have an important effect on the integrity of the glass); (2) molecular diffusion of the elements through the amorphous matrix, towards the surrounding solution, and (3) thermal diffusion (soret effect) of the elements in the glass, under the strong thermal gradients induced in the matrix by the heat produced by the waste. These three factors are also temperature dependent.

As we have discussed previously (Marsily *et al.* *Science* 197, 519; 1977), it becomes more and more obvious that the glassified waste will have to be stored in a cooling facility for 50 years or so after the extraction of the fuel from the reactor, before final disposal in a geological formation can be considered. This interim storage can perhaps take place in the final repository, but with a cooling mechanism (ventilation for instance). This will keep the temperature in the geological formation under 100 °C at 500 m depth, with a reasonable density of waste in the glass (of the order of 10 to 20%), and of glass in the geological formation (producing a heat load of the order 50 kW ha⁻¹ or less).

After 50 yr, the waste will produce 5 kW of heat per m³ of glass, at a 20% waste load. The rate of heat production 'decays' with a 'half life' of approximately 30 yr. It is of course

possible to reduce this rate by decreasing the waste load in the glass, but then the quantity of glass to be disposed of increases, and so does the area of the repository, the costs and so on. The suggested temperature of less than 100 °C will remain more or less steady for 1,000 yr due to both dissipation of heat in the rock and heat production decay. Accepting a temperature higher than 100 °C makes the safety evaluation of the repository much more uncertain (as a result of higher leach rates and mechanical instability of the rock and so on).

With such a temperature, and if a flow of water can reach the glass (that is, assuming the geological formation is not totally impervious and the container itself is not a good barrier), conservative estimates of the time needed to remove all the radioelements from the glass are in the range of a few thousand years. Much better results can be obtained if very little water flows through the repository, because the dissolution of the silica from the glass and the diffusion by the concentration gradients are then reduced; the leachability is also reduced if the silica content is increased, and the waste load reduced (for example to 10%, as in SYNROC). Note that other artificial barriers can also be added around the waste.

Now, what about the stability of the glass? The leach rates which I have considered above already assume that the glass matrix has suffered from thermal fracture as the canisters are decontaminated and cooled after fabrication. A factor of 20 is generally accepted for the increase in area per unit volume with respect to an undisturbed glass block of 150 l. Can other mechanisms increase this area? Many experiments, including resistance to radiation, with increased quantities of α -emitters (²⁴¹Am, ²⁴⁴Cm) to simulate the passage of 1,000 yr in 2 yr have, so far, given very good results. (If ²³⁹Pu is used instead of ²⁴¹Am, however, the mechanical resistance of the glass might be drastically reduced.) Only the possibility of crystallisation is considered dangerous, and this is one of the reasons why temperature should be kept as low as possible in the repository. Even then, crystallisation of the glass does not mean disaggregation. Phase separation (creation of a soluble molybdate phase) has been reported for some types of glass, but only during processing, and has not been suggested as a potential cause of instability.

However, it is well-known that artificial and natural glasses (obsidian, for example) brought to a high temperature and pressure can be metamorphosed into a clay-type material. That is what Ringwood has done: he brought samples of glass and SYN-

ROC to 350–400 °C and 1,000 bar, and found that the glass disintegrated (whereas SYNROC resisted). I have already discussed temperature, now what about pressure? The repository will lie at a depth of 500–1,000 m. After emplacement, it is generally agreed that it will be sealed with a buffer material (such as sand and bentonite, as proposed by the Swedes) and that grouting will be made to minimise the pore space of this buffer material. At the most, this grouting will be made at the lithostatic pressure, that is, of the order of 250 bar at 1,000 m. Now it is questionable whether the waste will be subjected to this pressure, or only to the hydrostatic pressure (for example, 100 bar). In any case, the pressure and temperature used by Ringwood seem inappropriate. Twenty-four hours at high temperature and pressure will never be equivalent to several thousand years in less severe conditions: the results obtained by Ringwood are as yet insufficient to prove that glass should be eliminated as a possible confining matrix.

On the other hand, the use of a crystalline structure instead of an amorphous matrix has always been attractive to geologists: elements trapped in a crystalline network are much less mobile, provided that the crystalline mineral has a very low solubility. This became evident in the study of the Oklo natural reactor which 'burnt' uranium approximately 2 billion years ago, in Gabon. Most of the radioactive 'waste' produced during the fission reaction has been found 'trapped' inside the crystalline structure of the uraninite mineral which formed the ore body. On the other hand, the elements which could not fit into the crystalline lattice of uraninite (because of a too small or too large ionic diameter) diffused and were apparently leached away.

One may then ask the following questions. Can the three minerals constituting SYNROC host all the radioelements present in the waste, and retain them with the same strength? Apparently only Cs, Sr and U have been actually tested on SYNROC B. Can a reasonable amount of waste (10% for example) be integrated in SYNROC, the present test having been done only with 1% of Cs, Sr and U? Is the stability and low leachability of SYNROC proved under more realistic conditions (water with low pH and more complex chemical composition than just NaCl, as may be found in a granitic environment)? Is radiation damage still insignificant for a 10% load of waste? The results obtained at the Battelle and Pennsylvania State University on a similar type of material ('supercaline') give approximately the same leach-

G. de Marsily is on leave at the University of Arizona Department of Hydrology and Water Resources.

ability as glass. And one must remember that stability of SYNROC at high temperatures and pressures does not automatically prove stability at other thermodynamic condition (consider for instance the weathering of granite). Is the industrial production of SYNROC as easy as Ringwood suggests? I confess to being slightly worried, for instance, over the control of the development of the crystalline phase inside the canister. This seems necessary in view of one result obtained by Ringwood, where insufficient mixing of the ingredients caused the appearance of an unknown 'accessory phase' rich in caesium, which was subsequently 'removed during leaching.' Also, the actual inclusion of ruthenium in hollandite is highly questionable in the process, given the high volatility of this element. One might also ask whether SYNROC can accept variations in composition of the waste (segregation of the liquid in the tanks) and the dissolution residues.

Nevertheless, the development of a confining matrix which would be stable for several million years in any environment is most desirable. If this could be achieved, the burden of proof of the safety of a repository would be transferred from the geologist to the manufacturer of SYNROC.

As a geologist, I cannot but support research in such a direction; as long as it is not used as an argument to delay further the search for a suitable geological formation which could contain the waste securely for a very long period of time. □

Cellulose microfibrils— an end in sight?

CELLULOSE is the most abundant macromolecule in the world; the figure usually quoted for its annual production is 10^{11} tonnes. Despite the obvious economic importance that such a figure implies, research into cellulose formation has so far failed satisfactorily to explain the way in which the functional unit of cellulose—the microfibril—is made. Viewed at its simplest, the microfibril is a crystalline association of long chains of β 1-4 linked glucose units, surrounded by a region of more amorphously associated chains. The whole structure is 6-20 nm wide, depending on its source, and intact microfibrils are of indeterminate length, certainly several microns long. The higher plant cell wall consists of a network of microfibrils associated with a matrix of other polysaccharides and proteins.

The formation of the microfibril can

be regarded as a two-stage process. The first stage is the biochemical formation of the polyglucan chains. Sugar units are added to the growing polymer as nucleotide complexes: the details of this process, and in particular the sites at which it occurs within cells are as yet unclear. The second process is the physical formation of the crystalline microfibril from the polyglucan. Here there are two rather distinct hypotheses to choose from.

The first supposes that the biochemical and physical processes occur more or less simultaneously, in other words that sugar units are added on the end of a pre-existing microfibril. Evidence for this is ultrastructural—the visualisation of ordered arrays of particles at the plasma membrane surface of algae having highly ordered cellulose walls. The particles are supposed to represent enzyme complexes engaged in the synthesis of the polyglucan chains. The evidence is persuasive, particularly since it can be further supposed that ordering of wall microfibrils might be mediated by movement of such terminating enzyme complexes within the surface of the fluid membrane. Attempts to show similar particulate complexes in higher plants however have for the most part been unsuccessful, although recent work using freeze-fracture techniques has been claimed to show terminal globuli associated with microfibril ends (Willison & Grout *Planta* 140, 53; 1978).

The alternative possibility is that the polyglucan first produced biochemically is in a soluble form, and that this intermediate associates to form the microfibril in a process not requiring direct structural linkage with the plasma membrane. This hypothesis has been recently examined by Colvin and his group, working with cellulose-producing bacteria (Colvin & Leppard *Can. J. Microbiol.* 23, 701, 1977; Colvin *et al. Can. J. Biochem.* 55, 1057; 1977; Sowden & Colvin *Can. J. Microbiol.* 24, 772; 1978). Colvin presents two lines of evidence in support of the idea that the biochemical and physical events of microfibril formation may not occur simultaneously. In structural terms, the authors describe a 'nascent' fibril, which is believed to represent an early stage in the formation of the classical microfibril. The nascent fibril has a diameter of up to 10 times that of the classical microfibril, and it consists of a dense crystalline core surrounded by an amorphous sheath which comprises most of the fibril's diameter. The nascent fibril is converted into the classical microfibril by dehydration. Thus in order to visualise the nascent fibril, only those techniques can be used which do not require the specimen to be dried before it is examined. Colvin

uses rapid freezing of 'never-dried' pellicles of bacterial cellulose, followed by deep etching of the specimen *in vacuo* and replication of the resulting etched surface. If the pellicles are first air dried, nascent fibrils are not seen, and the classical microfibril is formed.

These observations imply a change in thinking about the process of microfibril formation. The presence of nascent fibrils suggests that the acceptor for the sugar units may not be the end of a classical microfibril, but rather an unconsolidated polymer, or an association of such polymers. Direct structural involvement of membranes would not be required in this scheme.

Clearly for such a hypothesis to be viable it is necessary to demonstrate the reality of the postulated soluble intermediate polyglucan. This line of attack is the subject of the second of Colvin's three papers. The properties are described of a polysaccharide found in the medium in which the bacterial cells grow. This polysaccharide is prepared by precipitation from 60% ethanol, and further fractionated using ammonium sulphate precipitation. It appears to consist of chains of β 1-4 linked glucose units with on average a single glucose side chain on every third residue of the backbone. These branches would be expected to confer water solubility without affecting the basic linear shape of the molecule. As yet there is no direct evidence that this disperse family of polyglucans does in fact act as an intermediate in cellulose microfibril formation. Indeed, the branched structure of the polymer introduces a new complication in the form of an additional enzymic step to remove the single glucose side chains before crystallisation could take place. However, this work and its implications are at the very least sufficiently interesting to make a critical re-examination of the more established hypothesis worthwhile.

The key may after all lie with higher plant cells. Cellulose synthesis has been well studied biochemically in higher plants, but microfibril formation is naturally masked by the presence of a pre-existing cell wall. Now that the conditions for the formation of cell walls by isolated protoplasts are better understood, the time may be right to exploit this system in a more detailed way to examine *de novo* microfibril formation in higher plants. And of course, should Colvin's model prove to be applicable to cellulose formation in general, radical new thinking will be required to explain the differences in wall development which accompany cell differentiation in the higher organisms. □

Jeremy Burgess is at the John Innes Institute, Norwich.

Eddington on Einstein's new theory

In 1916 Arthur Eddington, at the age of 34, was Plumian Professor of Astronomy at Cambridge, director of the university observatory and Secretary of the Royal Astronomical Society. This piece, contributed for the then equivalent of News and Views was one of the earliest simplified expositions of the General Theory in English. The author's name was inscribed over the first paragraph by the editor, Sir Norman Lockyer.

GRAVITATION AND THE PRINCIPLE OF RELATIVITY.

ACCORDING to the principle of relativity in its most extended sense, the space and time of physics are merely mental scaffolding in which for our own convenience we locate the observable phenomena of Nature. Phenomena are conditioned by other phenomena according to certain laws, but not by the space-time scaffolding, which does not exist outside our brains. As usually expressed, the laws of motion and of electrodynamics presuppose some particular measurement of space and time; but, if the principle is true, the real laws connecting phenomena must be independent of our framework of reference—the same for all systems of co-ordinates. Of course, it may be that phenomena are conditioned by something outside observation—a substantial æther which plays the part of an absolute frame of reference. But the following considerations may show that the ideal of relativity is not unreasonable. Every observation consists of a determination of coincidence in space or time. This is sufficiently obvious in laboratory experiments; and even the crudest visual observation resolves itself into the coincidence of a light-wave with an element of the human retina. If, then, we trace the path of adventure of a material particle, it intersects in succession the paths of other particles or light-waves, and these intersections or coincidences constitute the observable phenomena. We can represent the course of Nature by drawing the paths of the different particles—on a sheet of paper in a two-dimensional case. The essential part of the diagram is the order of the intersections; the paths between the intersections are outside observation altogether, and are merely interpolated. The sequence of phenomena will not be altered if the paper is made elastic and deformed in any way, because the serial order of the intersections is preserved. This deformation of the paper corresponds to a mathematical transformation of the space in which for convenience we have located the phenomena.

Until recently the application of the principle of relativity was limited to one particular transformation, namely, a uniform translation of the axes. In this case there is a wide range of experimental evidence in support of the principle. In 1915 Prof. A. Einstein¹ finally succeeded in developing the complete theory by which the postulate of relativity can be satisfied for all transformations of the co-ordinates. Gravitation plays a part of great importance in the new theory, and therein lies much of the practical interest of Einstein's work.

¹ Einstein, "Die Grundlage der allgemeinen Relativitätstheorie." (Leipzig: J. A. Barth, 1916). A detailed account appears in *Monthly Notices*, 1916, No. 9, by Prof. W. de Sitter, giving the astronomical applications. See also an article by de Sitter in the *Observatory*, October, 1916.

No attempt is made to explain the cause of gravitation—as a kink in space or anything of that nature. But the extended law of gravitation is determined, to which Newton's law is an approximation under ordinary conditions. It has long been suspected that there must be some modification of the law when the bodies concerned are in rapid relative motion; moreover, the "mass" of a moving body no longer has a unique meaning, so that a further definition, if not extension, of Newton's law is clearly needed. Now, although we do not seek a cause of gravitation in the properties of space, it may well happen that the law of gravitation is determined by these properties. The inverse-square law represents the natural weakening of an effect through spreading out in three dimensions; we may say that it is determined by the properties of Euclidean space. There is, therefore, nothing unreasonable in proceeding, as Einstein does, to examine whether a more extended law is suggested by the properties of generalised space—that is, by geometry.

The way in which gravitation enters into the discussion may be seen from the following example. Suppose an observer is in a closed lift; let the supports break and the lift fall freely. To the observer everything in the lift will now appear to be without weight; gravity has been suddenly annihilated. The acceleration of his frame of reference (the lift) is equivalent to an alteration of the gravitational field. Now an acceleration of the axes is one of the transformations contemplated by the general principle of relativity, and it is therefore necessary to allow that the gravitational field depends on the choice of co-ordinates. There is a "local" gravity, just as there is a "local" time or magnetic field depending on the co-ordinates selected.

We can now take a brief survey of Einstein's procedure. Suppose that space and time are measured by a system of co-ordinates x_1, x_2, x_3, x_4 ; x_4 is the time, but there is no need to discriminate between it and the others. If there is a gravitational field at any point, it can be abolished (as in the example of the lift) by choosing new co-ordinates x'_1, x'_2, x'_3, x'_4 accelerated with respect to the old. The necessary transformation could be specified in various ways; the way chosen involves the element of length ds measured by coincidences with a standard scale, and therefore independent of the choice of co-ordinates. Since in the x' co-ordinates there is no gravitation to complicate matters, we can safely use the usual formula,

$$ds^2 = dx_1^2 + dx_2^2 + \dots$$

and this when transformed to the old co-ordinates takes the most general form,

$$ds^2 = g_{11}dx_1^2 + g_{22}dx_2^2 + \dots + 2g_{12}dx_1dx_2 + 2g_{13}dx_1dx_3 + \dots$$

The ten g 's depend on the transformation, and can

DECEMBER 28, 1916]

NATURE

329

be used to specify it. But they do more than that; they define the original gravitational field, since they specify how it can be got rid of. They usually vary from point to point, because a different transformation is needed to eliminate gravity at different points. In the new theory the g 's are regarded as ten gravitational potentials specifying the field; and, in fact, one of them, g_{44} , is approximately the same as the Newtonian potential ϕ , except for a factor.

The inverse-square law can be expressed by the well-known differential equation $\nabla^2\phi=0$. Evidently the new law of gravitation must be a generalisation of this—an equation, or set of equations, involving the ten potentials instead of one. Also, to conform to relativity, the new equations must be unaltered by a change of co-ordinates. If new co-ordinates are used the g 's will be different, but the relations between the new g 's and new co-ordinates must be the same as those between the old g 's and old co-ordinates. The possible sets of relations which satisfy this are very limited in number. This subject, known as the theory of tensors, has been worked out very fully by Riemann, Christoffel, and others, and the possible sets of equations can be classified and enumerated. From this limited choice we have further to pick out a set of equations which will reduce to $\nabla^2g_{44}=0$ as a first approximation, and that is found to leave only one possibility. There is just one set of ten differential equations (of which, however, only six are independent) which satisfy both conditions. Einstein takes these as expressing his generalised law of gravitation. It is important to notice exactly how much of this is geometry. Geometry shows that if the equations hold for a particular set of co-ordinates, they hold for every set. We abolish the "if," and so assert a new law of Nature.

It is further necessary to consider what must be the generalised equivalent of Poisson's equation $\nabla^2\phi = -4\pi\rho$, which supplants Laplace's equation when matter is present. The extension is not difficult, since it is found that the ten equations above mentioned are the expression of a generalised principle of least action as applied to gravitational energy. Now mass is considered to be simply electromagnetic energy, and since there is no reason to believe that electromagnetic energy will behave differently from gravitational energy in regard to least action, we have only to include both forms of energy together in the equations, treating them as equivalent. It is not possible to write down here these final equations, since a very elaborate notation is needed for their expression. Though highly complicated in form, they can be applied without excessive labour to the more simple problems.

One or two of the more elementary consequences of this theory were given by Einstein some years ago. A ray of light must be bent in passing

through an intense field of gravitation; thus a star seen close to the limb of the sun during an eclipse should appear displaced $1.7''$ from its usual position. The vibrations of an atom must be slower in an intense field, so that the lines of the solar spectrum should be displaced slightly to the red as compared with terrestrial spectra. It has not yet been possible to put these predictions to a satisfactory test, and it has been left to the completed theory to furnish the first opportunity of an appeal to observation. In this the new theory has scored a most signal success, for it has cleared up the most celebrated case of discordance in gravitational astronomy.

From his generalised law of gravitation Einstein has deduced that the elliptic orbit of a planet will rotate in the direction of motion at the rate of

$$\frac{24\pi^3}{V^2} \cdot \frac{a^2}{T^2(1-e^2)} \text{ radians per revolution of the planet.}$$

Here V is the velocity of light, and a , T , e are the semiaxis, period, and eccentricity of the orbit. If v is the velocity of the planet, the amount is practically $6\pi v^2/V^2$ radians per revolution. For Mercury this works out at $43''$ per century—just the amount of the outstanding discordance between observation and theory. The theory also gives rotations for Venus and the earth, but their orbits are so nearly circular that the effect is imperceptible to observation. For Mars, with its strongly elliptic orbit, the correction is more important, and sensibly improves the accordance between theory and observation.³

It is rather difficult to grasp the fact that the same laws of Nature may hold when some bizarre system of co-ordinates is chosen. Suppose an observer A uses rectangular co-ordinates, and B, through some kink in his mind, uses polar co-ordinates without realising that he is doing anything unusual. For A a ray of light can travel along the straight line $x=\text{constant}$; but evidently it cannot travel along the circle $r=\text{constant}$, which is B's idea of a straight line. The answer is that B through his peculiar system of measurement will suppose that he is in an intense gravitational field; he will calculate the curvature in the ray of light produced by this field; and, making allowance for it, he will find that the light actually travels along its theoretical curve (i.e. curve for B, but straight line for A). Thus the same general laws of Nature are satisfied for B as well as for A; and it might be difficult to decide which of them had got hold of the absolute rectangular co-ordinates.

A. S. EDDINGTON.

³ The discordance of the perihelion of Mercury (now removed) was nearly 40 times its probable error. Of the sixteen secular variations of the four inner planets, all are now accordant, except the node of Venus, which deviates by $4\frac{1}{2}$ times its probable error. Among sixteen residuals we should expect to find one of three times the probable error, so that the evidence for the remaining discordance is not very strong. There are besides unexplained variations of the longitudes of the moon and planets, but these are in a different category.

Albert Einstein: 14 March, 1879—18 April, 1955

A guide for the perplexed

Kenneth Brecher

This brief collection of direct and indirect quotations by or about Albert Einstein is offered as a tribute in honour of the centenary of his birth. The selection makes no attempt to be complete but does try to be representative of his attitude towards science and mathematics. As this selection is addressed to a primarily scientific audience, his views concerning his two most important creations, quantum theory and relativity, are particularly stressed toward the end.

The most beautiful experience we can have is the mysterious. It is the fundamental emotion which stands at the cradle of true art and true science. Whoever does not know it and can no longer wonder, no longer marvel, is as good as dead, and his eyes are dimmed.

from *The World as I See It*,
by A. Einstein (Philosophical
Library: New York, 1934)

I believe with Schopenhauer that one of the strongest motives that lead persons to art and science is flight from the everyday life, with its painful harshness and wretched dreariness, and from the fetters of one's own shifting desires. One who is more finely tempered is driven to escape from personal existence and to the world of objective observing and understanding. This motive can be compared with the longing that irresistibly pulls the town dweller away from his noisy, cramped quarters and toward the silent, high mountains, where the eye ranges freely through the still, pure air and traces the calm contours that seem to be made for eternity.

With this negative motive there goes a positive one. Man seeks to form for himself in whatever manner is suitable for him, a simplified and lucid image of the world, and so to overcome the world of experience by striving to replace it to some extent by this image. This is what the painter does, and the poet, the speculative philosopher, the natural scientist, each in his own way. Into this image and its formation, he places the centre of gravity of his emotional life, in order to attain the peace and serenity that he cannot find within the narrow confines of swirling, personal experience.

God is cunning but He is not malicious. (*Raffiniert ist der Herr Gott aber boshaft ist Er nicht.*)

inscribed at Princeton

Physics is essentially an intuitive and concrete science. Mathematics is only a means for expressing the laws that govern phenomena.

from *Lettres à Maurice
Solovine*, by A. Einstein
(Gauthier-Villars: Paris, 1956)

God does not care about our mathematical difficulties. He integrates empirically.

in *Quest* (page 279), by L.
Infeld (Gollancz: London, 1942)

How can it be that mathematics, being after all a product of human thought which is independent of experience, is so admirably appropriate to the objects of reality? Is human reason, then, without experience, merely by taking thought, able to fathom the properties of real things? In my opinion the answer to this question is, briefly, this: as far as the propositions of mathematics refer to reality,

they are not certain; and as far as they are certain, they do not refer to reality.

from "Geometry and
Experience", in *Ideas and
Opinions* (page 233), by
A. Einstein (Crown:
New York, 1954)

In the matter of physics, the first lessons should contain nothing but what is experimental and interesting to see. A pretty experiment is in itself often more valuable than twenty formulae extracted from our minds; it is particularly important that a young mind that has yet to find its way about in the world of phenomena should be spared from formulae altogether. In his physics they play exactly the same weird and fearful part as the figures of dates in Universal History.

from *Conversations with
Einstein*, by A. Moszkowski
(Horizon: New York, 1970)

What applies to jokes, I suppose, also applies to pictures and to plays. I think they should not smell of a logical scheme, but of a delicious fragment of life, scintillating with various colours according to the position of the beholder. If one wants to get away from this vagueness one must take up mathematics. And even then one reaches one's aim only by becoming completely insubstantial under the dissecting knife of clarity. Living matter and clarity are opposites—they run away from one another. We are now experiencing this rather tragically in physics.

in letter to Max Born, January
15, 1927, from *The Born-
Einstein Letters*, by M. Born
(Walker: New York, 1971)

It is in fact, nothing short of a miracle that the modern methods of instruction have not yet entirely strangled the holy curiosity of inquiry; for this delicate plant, aside from stimulation, stands mainly in need of freedom; without this it goes to wrack and ruin without fail.

from "Autobiographical
Notes", in *Albert Einstein:
Philosopher-Scientist*, edited by
E. A. Schilpp (Harper and
Row: New York, 1959)

The only rational way of education is to be an example—if one can't help it, a warning example.

To punish me for my contempt for authority, Fate made me an authority myself.

in *Albert Einstein: Creator and
Rebel* (page 24), by Banesh
Hoffman (Viking:
New York, 1972; Hart-Davis,
MacGibbon: London, 1973;
Paladin: London, 1977)

Great spirits have always encountered violent opposition from mediocre minds.

I remember a beautiful remark of his when he criticized a well-known American physicist. Einstein said he "couldn't really understand how anybody could know so much and understand so little"! Einstein always emphasized that you could know too many facts and get lost among them.

E. H. Hutten, in *Einstein:
The Man and His Achieve-
ment*, edited by G. J. Whitrow
(Dover: New York, 1973)

About ten years ago I spoke with Einstein about the astonishing fact that so many ministers of various denominations are strongly interested in the theory of

relativity. Einstein said that according to his estimation there are more clergymen interested in relativity than physicists. A little puzzled I asked him how he would explain this strange fact. He answered, a little smiling, "Because clergymen are interested in the general laws of nature and physicists, very often, are not." Another day we spoke about a certain physicist who had very little success in his research work. Mostly he attacked problems which offered tremendous difficulties.

By most of his colleagues he was not rated very highly. Einstein, however, said about him, 'I admire this type of man. I have little patience with scientists who take a board of wood, look for its thinnest part and drill a great number of holes where drilling is easy'.

Philipp Frank, "Einstein's Philosophy of Science", in *Reviews of Modern Physics*, 21, 349 (1949)

I might begin with a true story that some of you may know concerning a conversation between Einstein and the French poet Valery. When Einstein first came to Paris, a well known hostess achieved the triumph of having both Einstein and Valery in her drawing-room, and arranged for a conversation between the two that everyone else could listen to. As you know, Valery's mania was to say that he was more interested in the process of creation than in the actual opus which came out of this creative process . . . and he started asking questions of Einstein about how he worked.

"How do you work, and could you tell us something of this?" Einstein was very vague about it.

He said, "Well, I don't know . . . I go out in the morning and take a walk."

"Oh", said Valery, "Interesting, and of course you have a notebook and whenever you have an idea you write it out in your notebook."

"Oh", said Einstein, "No I don't".

"Indeed, you don't?"

"Well you know, an idea is so rare."

That is really as much as I think can be said as to really great creativity.

J. Monod, in *The Creative Process in Science and Medicine*, edited by H. A. Krebs and J. H. Shelley (Elsevier: New York, 1975)

He was asked whether he thought that everything could ultimately be expressed in scientific terms. Einstein replied: "Yes, that is conceivable, but it would make no sense. It would be as if one were to reproduce Beethoven's Ninth Symphony in the form of an air pressure curve."

G. Born, in *The Creative Process in Science and Medicine*, edited by H. A. Krebs and J. H. Shelley (Elsevier: New York, 1975)

During his Zurich stay the woman doctor, Paulette Brubacher, asked the whereabouts of his Laboratory. With a smile he took a fountain pen out of his breast pocket and said: "Here".

from *Albert Einstein: A Documentary Biography*, by C. Seelig (Staples: London, 1956)

The most important tool of the theoretical physicist is his wastebasket.

told by P. Morrison

Just as it is the pride of many people never to have any time, so it has been Einstein's always to have time. I

recall a visit I once paid him on which we decided to visit the astrophysical observatory at Potsdam together. We agreed to meet on a certain bridge in Potsdam, but since I was a good deal of a stranger in Berlin, I said I could not promise to be there at the appointed time.

"Oh," said Einstein, "that makes no difference; then I will wait on the bridge."

I suggested that that might waste too much of his time.

"Oh no," was the rejoinder, "the kind of work I do can be done anywhere. Why should I be less capable of reflecting about my problems on the Potsdam bridge than at home?"

in *Einstein: His Life and Times* (page 118), by P. Frank (Knopf: New York, 1947)

With his 'laboratory', 1948

Camera Press

The friendship of my thesis professor, Rudolf Ladenburg, and Einstein was a long one. They had been together in Berlin before coming to Princeton. Ladenburg liked to tell of their first meeting, about 1908, when he called upon Einstein in the Swiss Patent Office. Einstein told him that he was the first physicist that he had seen in five years. During these years Einstein had done much of his important work. He pulled out one drawer of his desk and said that it was his theoretical physics office. His duty of reading patents took little time, and he worked upon physics whenever he was free.

Y. Beers, *Am. J. Phys.*, 46, 506 (1978)

I never think of the future, it comes soon enough.

Who would have thought around 1900 that in fifty years time we would know so much more and understand so much less . . . Nowadays, one can be happy if one is not trampled down by the stampede of the buffalos.

in *Albert Einstein and the Cosmic World Order*, by C. Lanczos (Wiley: New York, 1965)

A theory is the more impressive the greater the simplicity of its premise is, the more different kinds of things it relates, and the more extended is its area of applicability . . . It [thermodynamics] is the only physical theory of universal content concerning which I am convinced that,

within the framework of applicability of its basic concepts, it will never be overthrown.

from "Autobiographical Notes", in *Albert Einstein: Philosopher-Scientist*, edited by E. A. Schilpp (Harper and Row: New York, 1959)

It was therefore quite a shock when he said, "But why should anybody be interested in getting exact solutions of such an ephemeral set of equations?". I remember very well this word "ephemeral". It meant that he did not consider his gravitational equations as the last word.

by C. Lanczos, in *Einstein: The Man and His Achievement* (page 49), edited by G. J. Whitrow (Dover: New York, 1973)

Press conference, New York, 1930

Popperfoto

But it [general relativity] is similar to a building, one wing of which is made of fine marble (left part of the equation), but the other wing of which is built of low grade wood (right side of the equation). The phenomenological representation of matter is, in fact, only a crude substitute for a representation which would do justice to all known properties of matter.

from "Physics and Reality" (1936), reprinted in *Ideas and Opinions* (page 311), by Albert Einstein (Crown: New York, 1954)

I can, if the worst comes to the worst, still realise that the Good Lord may have created a world in which there are no natural laws. In short, chaos. But that, there should be statistical laws with definite solutions, i.e., laws which compel the Good Lord to throw the dice in each individual case, I find highly disagreeable.

in *Albert Einstein: A Documentary Biography*, by C. Seelig (Staples: London, 1956)

You believe in a dice-playing God and I in perfect laws in the world of things existing as real objects, which I try to grasp in a wildly speculative way.

from letter to Max Born, quoted in *Albert Einstein: Philosopher-Scientist* (page 176), edited by E. A. Schilpp (Harper and Row: New York, 1959)

The present theory of relativity is based on a division of physical reality into a metric field (gravitation) on the one hand, and into an electromagnetic field and matter on the other hand. In reality space will probably be of a uniform character and the present theory be valid only as a limiting case. For large densities of field and of matter, the field equations and even the field variables which enter

into them will have no real significance. One may not therefore assume the validity of the equations for very high density of field and of matter, and one may not conclude that the "beginning of the expansion" must mean a singularity in the mathematical sense. All we have to realise is that the equations may not be continued over such regions.

in *The Meaning of Relativity* (page 129), fifth edition, by Albert Einstein (Princeton University Press: New Jersey, 1956)

Quantum mechanics is certainly imposing. But an inner voice tells me that it is not yet the real thing. The theory says a lot, but does not really bring us any closer to the secret of the 'old one'. I, at any rate, am convinced that He is not playing at dice.

from a letter to Max Born, December 4, 1926, from *The Born-Einstein Letters*, by M. Born (Walker: New York, 1971)

The Heisenberg-Bohr tranquilizing philosophy—or religion?—is so delicately contrived that, for the time being, it provides a gentle pillow for the true believer from which he cannot very easily be aroused. So let him lie there.

in a letter to E. Schrödinger, May 31, 1928, from *Letters on Wave Mechanics* (page 31), edited by K. Przibram (Philosophical Library: New York, 1967)

Is it conceivable that a field theory permits one to understand the atomistic and quantum structure of reality? Almost everybody will answer this question with "no". But I believe that at the present time nobody knows anything reliable about it. This is so because we cannot judge in what manner and how strongly the exclusion of singularities reduces the manifold of solutions...

One can give good reasons why reality cannot at all be represented by a continuous field. From the quantum phenomena it appears to follow with certainty that a finite system of finite energy can be completely described by a finite set of numbers (quantum numbers). This does not seem to be in accordance with a continuum theory, and must lead to an attempt to find a purely algebraic theory for description of reality. But nobody knows how to obtain the basis of such a theory.

in *The Meaning of Relativity* (page 165), fifth edition, by Albert Einstein (Princeton University Press: New Jersey, 1956)

You imagine that I look back on my life's work with calm satisfaction. But from nearby it looks quite different. There is not a single concept of which I am convinced that it will stand firm, and I feel uncertain whether I am in general on the right track... I don't want to be right... I only want to know whether I am right.

from *Lettres à Maurice Solovine*, by Albert Einstein (Gauthier-Villars: Paris, 1956)

One thing I have learned in a long life: that all our science, measured against reality, is primitive and childlike—and yet it is the most precious thing we have.

Immobilisation of high level nuclear reactor wastes in SYNROC

A. E. Ringwood, S. E. Kesson, N. G. Ware, W. Hibberson & A. Major

Research School of Earth Sciences, Australian National University, Institute of Advanced Studies, PO Box 4, Canberra 2600, Australia

The elements occurring in high-level nuclear reactor wastes can be safely immobilised by incorporating them within the crystal lattices of the constituent minerals of a synthetic rock (SYNROC). The preferred form of SYNROC can accept up to 20% of high level waste calcine to form dilute solid solutions. The constituent minerals, or close structural analogues, have survived in a wide range of geochemical environments for periods of 20–2,000 Myr whilst immobilising the same elements present in nuclear wastes. SYNROC is unaffected by leaching for 24 h in pure water or 10 wt % NaCl solution at high temperatures and pressure whereas borosilicate glasses completely decompose in a few hours in much less severe hydrothermal conditions. The combination of these leaching results with the geological evidence of long-term stability indicates that SYNROC would be vastly superior to glass in its capacity to safely immobilise nuclear wastes, when buried in a suitable geological repository. A dense, compact, mechanically strong form of SYNROC suitable for geological disposal can be produced by a process as economical as that which incorporates radwaste in borosilicate glasses.

SEVERAL countries propose to solidify the high level nuclear wastes arising from reprocessing of nuclear reactor fuel rods, and to bury the solids in suitable geological repositories. Because of the intensely radioactive nature of the waste (Table 1) this material must be prevented from reaching the biosphere for a period which may be as long as 1 Myr. This requires, among other things, that the waste be solidified in a form possessing extreme stability and resistance to leaching and alteration in appropriate geological environments.

The most popular procedure advocated by the nuclear power establishment during the past 25 yr has been to incorporate the radwaste into a borosilicate glass. The product typically contains ~25% of radwaste. There are, however, some serious disadvantages of this procedure which have become recognised only comparatively recently. Borosilicate glasses readily devitrify when subjected to the action of water and steam at elevated pressures and temperatures, for example at 300–400 °C and 300–1,000 bar^{2,3}. Pressure–temperature conditions in the lower end of this range may well be encountered by glass cylinders after burial in geological repositories. Moreover, it would be extremely difficult to design a repository in which groundwater can be prevented from gaining access to radwaste. (This includes

repositories in salt formations⁴). There is thus a high probability that glass cylinders will devitrify within relatively short intervals after burial. Devitrification in these conditions can cause a drastic increase in effective surface area and in leachability of certain highly dangerous species such as caesium and the actinides³.

It is unlikely that the problem can be avoided by reducing the proportion of waste and ageing the glass for 30 yr to achieve lower temperatures⁵. Detailed studies³ show that the mechanism of alteration is complex. One of the mechanisms involves diffusion of water into the glass structure. This precedes the actual devitrification and causes the interior of the glass to lose its strength. Another mechanism involves selective leaching of components from regions where devitrification is occurring, thereby producing a disintegrated material with a high degree of heterogeneity. Moreover, the rate of alteration is non-linear with time. Because of the complexity of the reaction mechanisms, it is not possible to predict the stabilities of glasses with respect to devitrification in geological environments at low temperatures in the vicinity of 100–150 °C.

Incorporation of radwaste in crystalline materials

McCarthy^{1,6} and Roy⁷ have previously recognised some of the uncertain aspects of immobilisation in glasses and have proposed that radwaste be incorporated in ceramic materials composed of crystalline phases. A phase assemblage of this

nature would be much closer to thermodynamic equilibrium than glass, so that the risks arising from devitrification of glasses would be avoided. These authors also described the basic crystal chemical principles underlying the incorporation of radwaste elements in crystalline phases.

There is, of course, an enormous range of crystalline phases, phase assemblages and methodologies which can be conceived for the purposes of storing radwaste elements. The particular strategy chosen by McCarthy led to the formulation of a series of materials designated by the general name of 'Supercalcine'. These materials are produced by adding ~50% of the oxides of Si, Ca, Al and Sr to the high level waste before calcination (Table 2). The above components are added in carefully-defined proportions so that during calcination, they will react with the components of radwaste to form a specific assemblage of desired crystalline phases. The preferred assemblage for waste derived from light-water reactors contains phases possessing apatite, fluorite, scheelite, pollucite and spinel-type structures.

McCarthy and Roy deserve credit for recognising at an early stage the disadvantages of glass as an immobilisation medium, and for perceiving the advantages of incorporating radwaste within crystalline phases. However, it is now clear that their Supercalcine strategy does not achieve many of the potential advantages of immobilising radwaste within crystalline phases. A detailed discussion of weaknesses of the Supercalcine strategy in this respect is given in refs 3 and 4.

An alternative method of radwaste immobilisation in crystalline materials was described by Ringwood⁴. This was based on incorporation of radwaste elements as dilute solid solutions in the constituent minerals of a synthetic rock—SYNROC. The preferred method of producing this SYNROC was to melt a mixture of TiO₂, BaO, SiO₂, ZrO₂, Al₂O₃, CaO and K₂O (Table 2, column I) at 1,300 °C and cool slowly to produce a synthetic rock composed of the minerals 'hollandite' BaAl₂Ti₆O₁₆, perovskite CaTiO₃, zirconolite CaZrTi₂O₇, Ba-felspar BaAl₂Si₂O₈, kalsilite KAlSiO₄ and leucite KAlSi₂O₆. Alternatively, this mineral assemblage could be produced by hot-pressing the above composition in subsolidus conditions. About 10% of radwaste calcine would be intimately mixed with the above SYNROC components before melting and crystallisation. Ringwood showed that nearly all the elements present in high-level waste (Table 1) were incorporated as dilute solid solutions within the individual minerals of SYNROC, and could therefore be immobilised for long periods when SYNROC was buried in a suitable geological environment.

The actual composition and mineral assemblage of SYNROC (Table 2) differs drastically from that of Supercalcine. There is also an important difference in concept. Because of the large proportion of radwaste (>50%) in Supercalcine, the radwaste

elements largely control the nature of the crystalline phase assemblage. This greatly restricts flexibility and yields a phase assemblage which possesses some undesirable characteristics^{3,4}. However, SYNROC contains only ~10% of radwaste. Thus, the 90% of added components controls the nature of the phase assemblage and the radwaste atomic species simply substitute in low concentrations within the crystal lattices determined by the major added components, as in nature. This provides a great deal of flexibility in selecting a crystalline phase assemblage with the most desirable immobilisation characteristics.

An important characteristic of SYNROC, therefore, is that its particular mineral assemblage (Table 2) remains essentially the same, whether the radwaste component amounts to 0%, 5%, 10% or even 20%. The advantages of this procedure are discussed more fully in refs 3 and 4.

We have since modified and simplified the original composition (termed SYNROC A in Table 2) by eliminating the silicate minerals Ba-felspar + kalsilite ± leucite. The modified version of SYNROC B is composed essentially of the minerals 'hollandite' + perovskite + zirconolite. Because of the absence of silicates, the titanium content is much higher and there is a superficial resemblance to the high-titanium ceramics developed by the Sandia Corporation⁷. However, Table 2 shows that the detailed chemical and mineralogical composition of SYNROC in fact differs fundamentally from that of the Sandia material.

Our main reason for developing SYNROC B was to incorporate radwaste caesium in the hollandite phase, which has proved to be exceptionally resistant to leaching. This was found to require the removal of kalsilite, leucite and Ba-felspar from the assemblage. Because of the absence of silicates, the melting temperature of SYNROC B is much higher than that of SYNROC A. Accordingly, we prefer to produce SYNROC B by hot-pressing and recrystallisation in the solid state at ~1,300 °C, as discussed subsequently.

Mineralogy of SYNROC B

When the SYNROC B bulk composition (Table 2, column 2) is hot-pressed at 1,200–1,400 °C, the minerals are found to possess hollandite, perovskite and zirconolite structures. Typical compositions of these minerals are given in Table 3.

'Hollandite': natural hollandite has the formula BaMn₈O₁₆, where manganese can occur in 2+, 3+, and 4+ valence states. There are, however, a large number of structural isotypes, including BaAl₂Ti₆O₁₆, in which the Mn²⁺ and Mn⁴⁺ ions of natural hollandite are replaced by Al³⁺ and Ti⁴⁺. The most abundant mineral in SYNROC A and B is BaAl₂Ti₆O₁₆. In subsequent discussions, this phase will be referred to as 'hollandite'.

Table 2 Comparison of SYNROC with alternative ceramic waste forms

Ca_2O	1.5	<0.1	<0.1
Total	99.7	100.2	100.5

* In other experiments, up to 7.5% SrO has been found in perovskite, with smaller amounts in zirconolite.

The hollandite structure is closely related to that of rutile, but differs in having tunnels parallel to the vertical axis in which very large atoms such as K, Rb, Cs, Ba, Sr and Pb may be stably bound. Moreover, many elements including Mg, Co, Ni, Cu, Cr, Fe, Mn, Mo, Rh, Ru, Sn and Zr are capable of replacing Al and Ti in the octahedral lattice sites. Because of the great flexibility and range of permitted ionic substitutions, and its resistance to leaching, 'hollandite' is a key component of SYNROC. We have also synthesised pure hollandite forms of $\text{Ca}_2\text{Al}_2\text{Ti}_6\text{O}_{16}$, $\text{K}_2\text{Al}_2\text{Ti}_6\text{O}_{16}$, and $\text{SrAl}_2\text{Ti}_6\text{O}_{16}$ and demonstrated the existence of extensive solid solutions with $\text{BaAl}_2\text{Ti}_6\text{O}_{16}$. Perovskite, CaTiO_3 : this mineral is capable of taking an extremely wide range of other elements into stable solid solution. The elements which are capable of replacing calcium in its lattice site include Sr^{2+} , Ba^{2+} , Na^{+} , all rare earths (REE^{3+}), Y^{3+} , Cd^{2+} , Mn^{2+} , Am^{3+} , Pu^{3+} whilst the elements capable of entering the titanium lattice site include Nb^{5+} , Zr^{4+} , Mo^{4+} , Pu^{4+} , Rh^{4+} , U^{4+} , Sn^{4+} , Ru^{4+} , Fe^{3+} , Cr^{3+} , Al^{3+} . Many more substitutions are known, but only those relevant to radwaste immobilisation have been mentioned. Zirconolite, $\text{CaZrTi}_2\text{O}_7$: this mineral possesses a distorted pyrochlore structure. A large number of pyrochlore isotypes are known and a wide range of atomic substitutions are possible. Thus, the eight-fold sites can be occupied by Na, K, Ca, Sr, Ba, Pb, Y, REE, Bi, Zr, U, Th, whilst Ta, Nb, Ti, Fe and Mn can substitute in the six-fold sites.

Incorporation of radwaste elements in SYNROC minerals

The relative proportions of different elements present in high-level wastes are given in Table 1. We have doped samples of SYNROC A and SYNROC B with 1–3% of non-radioactive isotopes of most of these elements. These compositions were then crystallised by appropriate heat-treatments at 1,150–1,350 °C and distributions of the tracers between coexisting phases were measured by electronprobe microanalyses. These experiments showed that nearly all the radwaste elements in Table 1 readily enter and form homogeneous solid solutions with the SYNROC minerals, as discussed elsewhere^{3,4}. The results are summarised in Table 4, showing which phase is the host for a particular element. On general crystal chemical grounds, we can be confident that the remaining rare earth elements will behave similarly to La, Gd and Y whilst the actinide elements (including plutonium, americium and curium) will behave similarly to uranium and/or the rare earths, entering zirconolite, and, to a lesser extent, perovskite. In SYNROC B, rubidium will doubtless behave similarly to potassium and caesium, thereby entering the hollandite phase. Phosphorus is found to combine with Ba and Ca to form minor amounts of an orthophosphate phase $(\text{Ba}, \text{Ca})_3(\text{PO}_4)_2$, whilst palladium and tellurium are reduced to the metallic state (Te as NiTe).

It is remarkable that almost the entire range of radwaste elements can be incorporated in only three crystalline phases, which are also thermodynamically compatible. This is a consequence of the structures and crystal chemical properties of these phases which permit an extremely wide range of ionic

substitutions. In principle, it would be possible to omit the perovskite phase, as the radwaste elements occurring in perovskite can also enter 'hollandite' and zirconolite. However, we retain perovskite in the SYNROC B assemblage because it preferentially accommodates ^{90}Sr , one of the most dangerous of radwaste isotopes. With this particular mineralogy, each of the three SYNROC B minerals thus accommodates preferentially a particularly hazardous radwaste element or class of elements—caesium enters 'hollandite', strontium enters perovskite, whilst actinide elements mainly enter zirconolite.

Accelerated leaching tests on SYNROC and glasses

We have investigated the relative stabilities of different waste forms by subjecting them to the action of water and aqueous solutions at elevated pressures and temperatures. The samples used were in the form of short cylinders with diameters of 2–4 mm. These were sealed in silver tubes, together with 12 times their volume of water or 10 wt % NaCl solution. After sealing, the tubes were placed in hydrothermal apparatus and subjected to the desired pressure-temperature conditions.

Borosilicate glasses possessing compositions proposed for radwaste immobilisation were completely devitrified and often disintegrated when subjected to the effects of pure water and 10 wt % NaCl solutions at temperatures of 350–400 °C and at 1,000 bar for 24 h. Extensive losses of caesium (50–95%), uranium (30–90%) and other cations were also observed.

In contrast, samples of SYNROC A (doped with 1% of Cs) remained unaltered when subjected to the effects of pure water at 1,000 bar, 24 h, and at temperatures up to 600 °C, demonstrating superiority to glass in this respect. However, when subjected to the action of 10% NaCl solution in the same conditions, kalsilite and leucite phases showed partial and extensive decomposition at 400 and 500 °C respectively, accompanied by loss of caesium. At 600 °C, these phases were completely decomposed and replaced by sodalite, with total loss of caesium. A similar series of experiments conducted on a sample of SYNROC A containing accessory pollucite ($\text{CaAlSi}_2\text{O}_6$) which is the host for caesium in Supercalcine and in the Sandia ceramic (Table 2, Columns III and IV) showed that this mineral was similarly unstable when subjected to the action of NaCl solutions in the above conditions. It seems then, that framework-type silicates such as pollucite, leucite and kalsilite may not be ideal for immobilising radwaste caesium in the presence of groundwaters containing dissolved sodium.

Samples of SYNROC B containing 1% each of Cs, Sr and U were next treated with pure water and 10% NaCl solutions in similar conditions to those used on glass and SYNROC A, but at 400, 500, 600, 700 and 800 °C. There was no significant alteration. The individual mineral phases remained stable and there was no measurable loss of Cs from 'hollandite', U from zirconolite or of Sr from perovskite. Moreover, there was no indication of entry of Na from the NaCl solution into the 'hollandite'. Similar leaching experiments were also carried out at 900 and 1,000 °C and at 5,000 bar for 24 h. In the 900 °C

Table 4 Summary of experimental data showing host phases for principal high-level waste elements introduced into SYNROC B

'Hollandite' $\text{BaAl}_2\text{Ti}_6\text{O}_{16}$		Zirconolite $\text{CaZrTi}_2\text{O}_7$	Perovskite CaTiO_3
Cs^{+}	Mo^{4+}	U^{4+}	Sr^{2+}
K^{+}	Ru^{4+}	Zr^{4+}	(U^{4+})
(Na^{+})	Rh^{3+}	Y^{3+}	(Y^{3+})
Ba^{2+}	Fe^{3+}	Gd^{3+}	(Gd^{3+})
	Cr^{3+}	La^{3+}	(La^{3+})
	Ni^{2+}		
	Fe^{2+}		

Actinide elements and rare earths preferentially enter zirconolite when this phase is present. However, they can also be accommodated by perovskite.

experiments, the 'hollandite' in the peripheral regions of the sample altered to rutile and caesium was lost into solution. However, the interior was unchanged. Zirconolite and perovskite throughout the entire sample were unaltered and retained their uranium and strontium quantitatively. At 1,000 °C, the samples were altered more extensively, but again, the central region was not affected.

The major minerals of SYNROC B exhibit a truly remarkable degree of resistance to hydrothermal alteration as compared to borosilicate glass, Supercalcine and SYNROC A. The extreme stability of these minerals justifies the conclusion that SYNROC B would constitute an excellent medium for radwaste immobilisation.

The remarkable ability of 'hollandite' to retain caesium and to resist exchange with sodium is probably a consequence of its crystal structure. Exchange can occur only through uniaxial diffusion of alkali elements through the narrow channels in the lattice parallel to the C axis. These are effectively blocked by Ba^{2+} ions which are tightly bonded because of their double charges and the caesium ions are thus locked-in. In contrast, open framework structures such as kalsilite, leucite and pollucite offer much easier three-dimensional access, thereby permitting exchange with sodium ions in solution and ultimate dissolution.

One problem encountered with the first batch of runs on SYNROC B arose from the loss of caesium from an unknown accessory phase (other than 'hollandite') during leaching. Broad-beam microprobe analyses of starting materials indicated the presence of 30–40% more caesium than could be accounted for by the 'hollandite'. This caesium was presumably present in another accessory phase which was removed during leaching. The formation of this phase was interpreted to result from incomplete equilibration during hot-pressing, due to imperfect mixing of components in the initial starting materials. This interpretation was supported by a subsequent series of four runs on modified SYNROC B compositions containing excess Al_2O_3 (13%) and, separately, excess TiO_2 (67%). The samples were mixed more thoroughly and hot-pressed at 1,350 °C, resulting in much coarser crystals and presumably, a closer approach to equilibrium. Samples of these runs were leached in 10% NaCl solutions for 24 h. No detectable losses of caesium from the bulk specimens were observed.

Radiation damage

Concern has been expressed that radiation damage to crystals of ceramic immobilisation media might enhance the solubility of radwaste elements in groundwater. Radiation damage, principally from actinide elements which emit α particles, causes disorder of the host lattice leading to the metamict state, sometimes accompanied by extensive volume expansion. However, experimental studies reviewed in ref. 4 show that, providing a radioactive element is substituting in a stable lattice site (such as U^{4+} substituting for Zr^{4+} in zircon), its solubility in aqueous solutions is not markedly increased by radiation damage. Aqueous solutions at elevated pressures and temperatures simply cause recrystallisation to the original state without loss of crystal-chemically compatible radioactive elements.

Most of the actinides in SYNROC would be incorporated in zirconolite. In nature, this mineral usually contains up to 1% of UO_2 and ThO_2 . Moreover, its structure is quite similar to that of pyrochlore, which commonly contains several per cent of UO_2 + ThO_2 . Natural zirconolite and pyrochlore minerals are usually metamict because of the intense accumulated radiation damage from α particles. Nevertheless, they seem to have survived in their host rocks for periods exceeding 2,000 Myr without losing appreciable amounts of uranium and thorium. The temperatures, pressures and leaching conditions encountered by the natural minerals were probably far more severe than those of any proposed radwaste repository. The stability of these minerals in natural conditions and their demonstrable capacity to retain uranium and thorium provide grounds for confidence that synthetic zirconolite in SYNROC will be capable of immobilising the actinide elements for the required period of

~1 Myr, when buried in a carefully-chosen geological-geochemical environment.

In view of the the proved stability of 'hollandite' and perovskite in SYNROC B as demonstrated by their extreme resistance to leaching in experimental conditions, we can be confident that these minerals will be able to immobilise caesium and strontium for the required decay period of ~1,000 yr when SYNROC is buried in a suitable geological repository.

Operation of the SYNROC process

Our preferred process for immobilising radwaste is illustrated in Fig. 1. It is envisaged that high level waste (HLW) solution would continue to be flash-heated to produce 'calcine' as at present. SYNROC would be produced by a similar process from an aqueous solution-suspension containing the components in their correct proportions. Oxide mixtures produced by this procedure possess a high degree of reactivity and homogeneity.

About 90% of SYNROC would then be intimately mixed with ~10% of HLW calcine. The mixture would be introduced into a thick-walled cylindrical nickel container and uniaxially cold-pressed to ~70% of its theoretical density. A thick nickel lid would then be placed on the cylinder, separated by a thin copper seal.

Fig. 1 Flowchart for the immobilisation of radwaste in SYNROC and sealing of the resultant material in thick-walled nickel canisters.

The entire assembly would then be hot-pressed, either uniaxially or isostatically, at a temperature of 1,200–1,300 °C. In these conditions, rapid and complete subsolidus equilibration and recrystallisation of HLW calcine and SYNROC components occur, leading to the formation of a well-crystallised SYNROC mineral assemblage containing the HLW calcine components in solid solution. The mineral assemblage is mechanically strong and close to theoretical density.

During hot-pressing, the nickel container is mobile and flows inwards as the volume of the SYNROC contracts. The lid is sealed on to the container simultaneously by the copper, which melts at a lower temperature and alloys with nickel on either side. Two important advantages accrue from the above procedure. First, the formation of crystalline SYNROC in its terminal state and final encapsulation and sealing of the SYNROC in a metal capsule are performed in a single operation. Second, volatile components such as caesium and ruthenium are quantitatively retained by SYNROC minerals during the hot-pressing operation, and become permanently incorporated in the lattices of SYNROC minerals as described earlier. Radioactive contamination of the production plant and of the environment is thereby minimised. In contrast, during the production of borosilicate glasses, substantial amounts of caesium, ruthenium and other volatile elements are lost by

volatilisation. The recovery of these elements for recycling is an expensive operation.

Conclusion

If our society is to take advantage of the potential benefits of nuclear power, there can be no excuse for any policy which does not use the most advanced technology to safeguard future generations from the attendant dangers of high level nuclear wastes. It can hardly be claimed that immobilisation of radwaste in borosilicate glasses, currently favoured by the nuclear power establishment, satisfies this requirement.

We have demonstrated that a form of synthetic rock, SYNROC, can be produced which is vastly superior to glass in its ability to immobilise radwaste for long periods in appropriate geological-geochemical environments. Because of the simplicity of the production technique, and the absence of a need to

recycle escaping volatiles such as Cs and Ru, the cost of producing SYNROC may be comparable to, or even less than, glass.

SYNROC is immune from devitrification and is composed of mutually compatible phases, which possess crystal structures identical to those of minerals which are known to have survived in geological environments at elevated pressures and temperatures for periods of 20–2,000 Myr and to have retained radioactive elements for these periods. This fact provides grounds for confidence that the far shorter immobilisation period required for radwaste can be attained in the much less extreme pressure-temperature conditions present in a suitable geological repository. This confidence is reinforced by direct accelerated leaching tests at elevated pressures and temperatures.

Note added in proof: Pudovkina *et al.*⁹ have since observed that the mineral zirkelite which occurs in the gem gravels of Sri Lanka and contains up to 20% (UO₂+ThO₂), possesses the zirconolite structure.

Evidence for late Precambrian plate tectonics in West Africa

R. Black, R. Caby, A. Moussine-Pouchkine, R. Bayer, J. M. Bertrand, A. M. Boullier, J. Fabre & A. Lesquer

Centre Géologique et Géophysique, Université des Sciences et Techniques du Languedoc, 34060 Montpellier Cedex, France

In the Gourma and Iforas regions (Mali) rifting occurred around 800–850 Myr ago along the eastern margin of the West African craton with a triple point in Mali, the Gourma being interpreted as an aulacogen. Oceanic closure around 600 Myr led to a collision between the passive continental margin of the West African craton and an active continental margin to the east displaying island arc and marginal trough volcano-clastic assemblages bordering a deformed continental mass intruded by a high-level batholith. The suture is marked by a string of positive gravity anomalies corresponding to the emplacement of ultrabasic and basic rocks including perhaps ophiolites. East-West shortening was accompanied by the translation onto the West African craton foreland of nappes including internal nappes displaying high pressure-low temperature metamorphism assemblages.

A CONTROVERSIAL subject in orogenesis^{1,2} is whether plate tectonics had an important role in the Proterozoic^{3,4} or whether *in situ* ensialic models fit the facts^{5,6} in the best way. To seek an answer, attention has been focused on the Pan-African, the youngest and best preserved of Precambrian orogenic belts. In the past few years a detailed geological and geophysical investigation has been carried out on the critical Iforas-Gourma region in Mali^{7–10} (Fig. 1), an area of about 300,000 km², crossing the West African craton and the Pan-African mobile belt to the East. The results show convincing evidence of a Wilson cycle ending with collision between a passive continental margin and an active continental margin.

Pre-Pan-African rifting and the Gourma aulacogen

The West African craton, stable since 1,700 Myr, is partly covered by thin flat-lying cratonic sediments younger than 1,000 Myr (refs 11, 12), but along its eastern margin the Gourma basin is characterised by deep subsidence with an accumulation of over 8,000 m of sediments⁹ (Fig. 2). The observed sedimentary sequence with an early terrigenous clastic phase at the base (formations I and II), followed by differentiated carbonate deposits indicating lateral passage platform-slope-trough (formation III) and ending with prograde continental clastic sediments (formations IV and V) is typical of a passive margin¹³. Furthermore analysis of palaeocurrents in the overlying Bandiagara Sandstone Group shows a converging drainage pattern centred on the Gourma with transport from the south-west and west. The shape of the basin, as defined by the distribution of slope sedimentary facies (breccias, turbidites) in the carbonate sequence and by the gravity pattern, is that of a trough orientated WSW-ENE representing a gulf of subsidence within the West African craton, which here forms an embayment. It presents all the characteristics of a typical aulacogen¹⁴. A detailed sedimentological study will be given elsewhere. Gravimetrically it is marked by positive anomalies which can be traced westwards across the West African craton and this suggests a deep crustal heavy source¹⁵. We conclude that a major change in sedimentation occurred around 850–800 Myr ago with rifting along the eastern margin of the West African craton with a triple point in Mali: the Gourma is thought to be a failed arm which has evolved as an aulacogen, a comparable situation with that of the Benue trough with respect to the Gulf of Guinea in the Cretaceous⁴.

Fig. 1 Major structural units of the Iforas-Gourma region (Mali).

The associated magmatism would be represented to the North in northwestern Hoggar by the intrusion at around 800 Myr of gabbros and ultrabasic rocks into Upper Proterozoic quartzites and dolomites of shelf type^{12,16}, and by the presence of deformed north-south dyke swarms of alkaline and peralkaline metarhyolites, undersaturated soda-trachytes and metaphonolites superimposed on basic dyke swarms which may represent the roots of a pre-Pan-African palaeorift¹⁶. In northeastern

Gourma at Amalaoulaou gabbros and ultrabasic rocks are believed to have intruded the base of the crust at ~850 Myr before high pressure-high temperature granulite conditions and to have been tectonically emplaced around 600 Myr at a high level in the suture zone (Lancelot and de la Boisse, personal communication).

The suture

Oceanic closure 200 Myr later during the Pan-African is marked by a suture outlined by a string of positive gravity anomalies with amplitudes of over 30 mgls locally attaining 80 mgls which may be followed over a distance of 2,000 km and which correspond in the Iforas-Gourma region to the position of basic and ultrabasic complexes (mainly layered metagabbros and quartz gabbros) and may include ophiolites (Fig. 3). Interpretation of profiles across the anomalies¹⁵ using the inverse approach¹⁸ and linear programming¹⁹ shows that the structures, considered as homogeneous bodies with densities $>2.8 \text{ g cm}^{-3}$ and generally $>2.9 \text{ g cm}^{-3}$ continue to depths varying from 6 to 20 km. Geometry shows that bodies with a density of 3 g cm^{-3} must be unrooted. In shape they generally show an easterly dip which is in accord with the general movement pattern with thrusting towards the West African craton and with direct field observations made along the banks of the Niger.

South-west and west of the suture

In the Gourma (Figs 1, 4) nappes outcrop over a zone 300 km by 50–80 km wide²⁰. The internal nappes (mainly micaschists and quartzites) characterised by high pressure-low temperature metamorphism display flat-lying foliation. Foliation planes bearing phengite cut earlier sharp folds and the grade of metamorphism increases to the south-west where it attains eclogite conditions with a very pure jadeitic pyroxene (de la Boisse, personal communication). Stretch lineation association with NE-SW minor folds perpendicular to the general strike, are well developed within the nappes and along the lower grade mylonitic quartzite soles of the nappes. In northern Gourma the internal nappes come into direct contact with the para-autochthonous folded greenschist facies Gourma formations by underthrusting towards the south-west; to the south they are faulted against the Bourré Massif. The Bourré Massif²¹ is a sub-vertical horst of Eburnean granite dated at $2,080 \pm 20 \text{ Myr}$ ²² intrusive into subsequently retrograded amphibolite facies Birrimian sediments, overlain in unconformity by upper Proterozoic sericite quartzites and basal polygenic conglomerate. The horst was extruded after the passage of the external nappes, a situation comparable to that of the Mont Blanc in the western Alps. The external nappes are sub-horizontal and probably pellicular. They consist essentially of schistose formations belonging to the passive margin displaying greenschist facies metamorphism devoid of high pressure conditions. Over large areas one observes an upright succession and flat schistosity and a-type lineations within the nappes. The Gourma formations I–V described above¹³ as forming a pre-Pan-African aulacogen have been strongly deformed to form the para-autochthonous foreland. Major folds are overturned to the south-west and are superimposed on early pre-nappe east-

Fig. 2 Schematic SSW-NNE section showing variations in facies and thickness of the Gourma formations I–V.

west folds⁹. Between the front of the nappes and Hombori (100 km) several tens of kilometres of shortening implies a 'décollement' with respect to the underlying basement. The non-metamorphic Bandiagara Sandstone Group overlies in unconformity the Gourma Formations I-V and has been affected by a later phase of folding.

Fig. 3 Simplified Bouguer anomaly map of the eastern margin of the West African craton.

Four-hundred kilometres further north, in the Taounant region two flat-lying superimposed nappes have been mapped directly overlying eroded Eburnean (2,000 Myr old) basement. The lower one consists of a mylonitised unit of quartzites-dolomites presumably belonging to the passive continental margin whereas the overlying one is composed of strongly epidotised metabasalts and diabbases containing a blue amphi-

bole, which are thought to come from an oceanic domain to the east. Similarly to the South in the Timetrine, the quartzites, meta-arkoses, phyllites, large serpentine bodies and metabasalts with blue amphibole, are also interpreted as nappes, but here the relationships with the Eburnean basement are obscured by the Cretaceous.

A characteristic feature west of the suture is the total absence of autochthonous Pan-African magmatism. To the east of the suture a strongly deformed zone ~100 km wide is composed of a late Upper Proterozoic volcano-clastic assemblage. It consists of flysch-like metagreywackes with turbidites, conglomerates composed exclusively of volcanic and plutonic pebbles, dacitic breccias and meta-basalts and later meta-andesites volcanic greywackes and a terrigenous flysch unit, suggesting island arc and marginal sea environments, still active during the earlier deformation of the more internal continental domain of the Iforas, a situation similar to that of the upper Cretaceous to Mid-Tertiary flyschs of Western Alps. This assemblage is comparable to that of the 'Série verte' described 300 km further north in North-west Hoggar¹⁶ where geochemical studies have shown the immature nature of the greywackes²³ and the probable derivation of andesites in liaison with a subduction zone by partial melting of the mantle followed by low pressure fractionation²⁴. This zone is injected by a considerable volume of predominant pre-tectonic ultrabasic rocks, gabbros and diorites the volume of more acid terms, tonalites and adamellites increasing eastwards. This accretion zone, apparently devoid of an ancient sialic substratum, follows the sheared western margin of the Iforas. It is significant that greywacke formations with associated calc-alkaline magmatism which are widely developed in western Hoggar and the Iforas are totally absent west of the suture. Such an absence would be explained by the former existence of an ocean separating two continents.

The Iforas is a highly deformed sheared continental domain of 2,000 Myr old granulite basement with remnants of supracrustal platform deposits (quartzites and dolomites) overlain by late Upper Proterozoic marginal sea volcano-clastic sediments including a possible tillite intruded by abundant pre-, syn- and post-tectonic granitoids. A zone of late high temperature-low pressure metamorphism with the local occurrence of granulite facies rocks, charnockites and norites (Aguelhoc, Iforas, Egalis, North-west Hoggar) coincides with the westernmost known area of sialic rock and its Upper Proterozoic cover²⁰. A vast composite late to post-tectonic calc-alkaline batholith capped by flat-lying rhyolitic lavas (Nigritian)¹⁰ and cut by sub-alkaline and alkaline ring-complexes occupies the external zone of the continental domain. It coincides with a regional positive gravity anomaly. Emplacement occurred in a zone subjected to pronounced vertical uplift leading to unroofing during the Pan-African. Existing U-Pb data on Zircons (Lancelot, personal communication) suggest this late batholith to have been emplaced in a relatively short interval between 615 and 590 Myr, the dates 616 ± 11 Myr and 613 ± 3 Myr corresponding respectively to a diorite and quartz monzonite, and 586 ± 13 Myr to a hedenbergite-hastingsite-perthite granite belonging to the Kidal ring-complex. Magmatic activity in this zone, however, must have taken place over a long period of time, as the late batholith cuts foliated diorites corresponding to a deeply eroded pre-tectonic palaeobatholith about 700 Myr old. A striking feature of the batholith is the presence of spectacular dyke swarms. Early east-west striking swarms consist essentially of subordinate basic dykes, quartz-microdiorites micro-adamellites and felsites which locally were truncated by high-level adamellite and perthite granite. They are cut by important north-south swarms composed of subordinate basic dykes and several generations of quartz microsyenite, granophyres and rhyolites which can be followed over a distance of over 250 km in the axis of the batholith and which coincide with the Nigritian rhyolite fields and the alignment of ring-complexes. In a different context the batholith displays features reminiscent of an Andean-type batholith²⁵. The general disposition of calc-alkaline magmatism east of the suture suggests an easterly

Fig. 4 Schematic geological sections across the suture. The location of the sections A-B, C-D, are indicated in Fig. 1.

dipping palaeo-subduction zone and the high pressure–low temperature metamorphism of the internal nappes of the Gourma would fit with this picture. The late alkaline rocks in the ring-complexes may be related to verticalisation of the Benioff plane accompanied by a diapiric rise of mantle material east of the suture²⁶.

General movement pattern

The Eburnean basement and supracrustal Upper Proterozoic formations of the Iforas have a complex structural and metamorphic history. Early Pan-African intracontinental deformation dated by the earliest syntectonic granites at 693 ± 0.3 Myr (Renaud Andreopoulos, personal communication) and which took place in barrowian metamorphic conditions generated large northwesterly moving crystalline nappes which were subsequently refolded, leading to considerable tectonic thickening and locally pronounced NW–SE metamorphic gradients²⁷. This early phase of deformation produced ENE–WSW structures which have also been observed in the accretion zone and suggest an early collision still not well defined. Late Pan-African deformation directly related to collision with the West African craton resulted in considerable east–west shortening in western Iforas and in the translation of nappes onto the foreland west and south-west of the suture. A characteristic feature east of the suture is the spectacular development of shear belts with a complex history. There is evidence for early sinistral movement along N° 20 trending shear belts and in the closing stages of collision for dextral movement on north–south belts leading to the northwards displacement of western and central Iforas with respect to eastern Iforas. Molassic sediments similar to the ‘Série Pourprée’ of western Hoggar dated at around 530 Myr (ref. 7) occur in grabens and fill a north–south palaeo-rift on the West-African craton between the suture and Timetrine-Taounnant where it is associated with under-saturated syenites and carbonatites. Late movements as young as the Upper Cambrian produced open north–south folds in the molassic sediments and a system of conjugated NNW sinistral and ENE dextral wrench faults, a system largely developed throughout the Pan-African mobile zone of West Africa²⁸.

Conclusions

All the evidence points to a modern-type orogenic belt involving a collision during the closing stages of the Pan-African, between the passive continental margin of the West African craton and

the active continental margin of an eastern continent. This conclusion fits the recognition of obducted ophiolites at Bou Azzer (Morocco) along the northern margin of the West African craton²⁹ and supports the collision hypothesis advanced for the Togo–Benin segment³. Looking at the Touareg shield (Hoggar, Air, Iforas) as a whole, the general pattern of shear belts and late Pan-African deformation seen at an eroded level, shows striking analogies with the tectonic pattern of Asia produced by the collision of India³⁰. Palaeomagnetic evidence suggests important horizontal displacement during the Pan-African³¹, and proposed reconstructions for 800 Myr and 675 Myr indicate open situations between North America and Gondwanaland and oceanic closure at 600 Myr (refs 32, 33). As no measurements exist for the West African craton, these results are not incompatible with the former presence of a pre-Pan-African ocean situated east of the West African craton.

This article presents the results obtained by a team composed of E. Ball, R. Bayer, J. M. Bertrand, R. Black, H. de la Boisse, A. M. Boullier, R. Caby, J. Ducrot, J. Fabre, J. R. Lancelot, M. Leblanc, A. Lesquer, A. Moussine-Pouchkine, P. Morel-à-l'huissier, U. Renaud-Andreopoulos, J. Sarfati of the Centre Géologique et Géophysique de Montpellier, I. Davison and L. I. Wright of Leeds University and H. Ba and S. Ly of the Direction Nationale de la Géologie et des Mines of Mali. The project was carried out in collaboration with the Direction Nationale de la Géologie et des Mines of Mali and with ORSTOM for the gravity survey. Structure of the human fetal globin gene locus

We have derived a 'map' of restriction enzyme sites in and around the human γ -globin genes. This has enabled us to show that there are two γ -globin genes per haploid set, that the genes contain 'introns' within the same regions of DNA as the human β and δ -globin genes, and that the genes are 3,500 base pairs apart. We conclude that the correct gene organisation of the human β -like globin locus is $\gamma^A\gamma^B$.

DURING human fetal life, the major haemoglobin is HbF, consisting of two α -globin and two γ -globin chains ($\alpha_2\gamma_2$). In the last stages of fetal development, a switch occurs from γ -globin synthesis to adult β -globin synthesis; by a few weeks after birth, the major haemoglobin is HbA ($\alpha_2\beta_2$) accompanied by a much lower level of HbA₂ ($\alpha_2\delta_2$)¹. In some populations (such as Saudi Arabians), in most persons at times of erythropoietic stress (as in severe anaemia, β -thalassaemia, or sickle cell disease) and in pregnancy, the proportion of HbF in adult peripheral blood rises. In addition, in the rare condition known as hereditary persistence of fetal haemoglobin (HPFH) there is no HbA or HbA₂ and the person, who is clinically asymptomatic, survives solely on HbF (refs 2, 3).

It is known that there are at least two non-allelic γ -globin genes, one of which codes for a γ -globin chain with glycine and the other with alanine at amino acid position 136 of the 146 amino acid γ -chain (γ^G and γ^A respectively)⁴. In people with a mutation at some other position, either the γ^G or the γ^A -globin chain shows the mutation, but never both. It can be concluded that there must be at least two γ -globin genes per haploid genome, one each for the γ^G and γ^A -globin chains. Molecular hybridisation to cellular DNA of γ -globin complementary DNA supports this conclusion⁵⁻⁷.

However, the chain synthesis ratios of γ^A and γ^G are not those predicted if protein synthesis reflects gene number, and therefore it has been suggested that there are three or four γ -globin genes per haploid genome⁸. It has also been suggested that a third γ -globin gene may occur, so-called γ^T , coding for HbF_{Sanchez}, with threonine rather than isoleucine in position 75 (ref. 9). γ^T expression varies greatly among individuals and may represent either a third non-allelic γ -globin gene, or a commonly occurring allele of one of the existing genes. It is not yet possible to distinguish genetically between these alternatives.

We have recently reported the physical map of the human δ and β -globin gene loci¹⁰ as have others¹¹. Here we describe similar experiments which allow the mapping of the human γ -globin genes within their surrounding DNA sequences.

The development of techniques for the mapping of single-copy genes¹²⁻¹⁵ makes it possible to construct a physical map of restriction enzyme sites in and around the γ -globin genes. Normal human placental DNA is digested with restriction

enzymes and denatured. The fragments are separated by electrophoresis on a 1.2% agarose gel, transferred from the gel to a nitrocellulose filter using the method of Southern¹² and hybridised with ³²P-labelled pH γ G1 DNA followed by autoradiography to reveal the position of the fragment containing γ -globin gene sequences. pH γ G1 is a pCR1-derived recombinant that contains 500 base pairs of double-strand complementary DNA prepared from human γ -globin mRNA¹⁶. The limitations of this technique have been extensively discussed^{10,12,14,15}.

Our approach to mapping the γ -gene locus has been to identify a restriction endonuclease which gives only a single fragment containing all the γ -globin gene sequences hybridising to the specific γ -globin recombinant probe, to locate the gene sequences within this fragment by making use of restriction enzymes which are known to cleave within the globin coding sequence, and to distinguish between the several (in this case, two) gene sequences by identifying a restriction site present in one and absent in the other.

Table 1 Summary of sizes of γ -globin gene fragments generated by a variety of restriction enzymes in single and double digests

<i>Bgl</i> III	<i>Bam</i> HI	<i>Eco</i> RI	<i>Pst</i> I	<i>Xba</i> I	<i>Bgl</i> III + <i>Bam</i> HI	<i>Bgl</i> III + <i>Eco</i> RI
13	15.0	6.5	10.0	7.5	6.0	3.0
	5.0	2.5	5.0	5.0	5.0	2.5
	2.6	1.65	4.0	3.7	2.1	1.65
		0.65	0.9			0.65
<i>Bgl</i> III + <i>Pst</i> I	<i>Bgl</i> III + <i>Xba</i> I	<i>Bam</i> HI + <i>Eco</i> RI	<i>Bam</i> HI + <i>Xba</i> I	<i>Eco</i> RI + <i>Pst</i> I	<i>Pst</i> I + <i>Xba</i> I	
5.0	6.0	2.6	7.5	4.0	5.0	
2.2	5.0	1.65	5.0	1.8	3.7	
0.9	2.25	1.05	2.6	1.6	0.9	
		0.65		0.8		

Sizes are in kilobase pairs.

High molecular weight DNA was isolated from placentae of three normal infants of English, Welsh and Dutch ancestry. The DNA was cleaved with the restriction enzyme BglII, and after electrophoresis, transfer and hybridisation to ³²P-labelled pH γ G1 DNA only a single fragment of about 13 kilobases is seen. This fragment contains all the γ -globin gene sequences in human DNA. (All γ -globin gene fragment sizes are presented in Table 1.)

Several restriction endonucleases are known to cleave the γ -globin gene sequence from direct analysis of plasmid recombinants constructed with cDNA prepared from γ -globin mRNA¹⁶⁻¹⁸. Table 2 lists these enzymes, together with the corresponding amino acid positions coded for at the cleavage site. BamHI and EcoRI cleave both the γ^A and the γ^G genes, in

Table 2 Restriction enzyme sites within the A_γ or G_γ coding sequence

	A_γ	G_γ
<i>EcoRI</i>	121–122	121–122
<i>BamHI</i>	99–100	99–100
<i>PstI</i>	135–136–137	None
<i>XbaI</i>	None	None
<i>BglII</i>	None	None

Sites given are for the amino acids coded for by the restriction site in the appropriate γ -globin gene. Numbering is from the N(5') terminus of the protein chain. The positions of the *EcoRI* and *BamHI* sites are from refs 16 and 17; the *PstI* site from ref. 18, and the absence of *XbaI* and *BglII* sites from our unpublished data.

the same coding positions as for the human β and δ -globin genes, whereas *PstI* cleaves only the A_γ gene and not the G_γ (ref. 18). It is known that the coding sequence for A_γ contains a *PstI* site at the position coding for amino acids 135–136–137 (–CTGCAG–). This site is absent from the G_γ gene because of the presence of glycine rather than alanine at this position of the amino acid chain, giving a sequence altered to (–CTGGAG–) which is not cleaved.

When normal DNA is cleaved with *EcoRI*, four fragments hybridising to the γ -globin probe are obtained, of sizes 6.5, 2.5, 1.65 and 0.65 kilobases (Fig. 1). Assuming at this stage that there are two genes, this is consistent with the presence of at least one additional *EcoRI* site between the two genes. If this prediction is valid, these four fragments include two derived from the 3' end of the genes and two derived from the 5' end.

A double digest with *BglII* and *EcoRI* again gives four fragments (Fig. 1), three of which (at 2.5, 1.65 and 0.65 kilobases) are identical to those from an *EcoRI* digest and one of which, of 3.0 kilobases, is new and replaces the band of 6.5 kilobases, from which it must be derived. (It is too large to be

generated from any other *EcoRI* fragment). Therefore an *EcoRI* site internal to one of the γ -globin genes must be located 3.0 kilobases from one of the bounding *BglII* sites, and a second *EcoRI* site must lie 3.5 kilobases to the other side of this *BglII* site. The three smallest *EcoRI* fragments are not cleaved by *BglII* and therefore must lie entirely within the large 13-kilobase *BglII* single digest fragment.

BamHI single digests of human DNA give three hybridising fragments of 15, 5.0 and 2.6 kilobases (Fig. 1). As both genes contain a *BamHI* site, these three fragments could result from the *BamHI* cleavage of each gene, with no additional *BamHI* site in the DNA sequence between the two genes. The two *BamHI* sites are localised within the 13-kilobase *BglII* fragment, as shown using a double digest of *BamHI* plus *BglII*. The 15.0-kilobase *BamHI* fragment is cleaved by *BglII* to give a 6.0-kilobase double digest fragment; the 2.6-kilobase *BamHI* is cleaved by *BglII* to give a 2.1-kilobase double digest fragment (Fig. 1). The 5.0-kilobase *BamHI* fragment is not cleaved by *BglII*. Thus, *BamHI* sites are located 6.0 and 2.1 kilobases, respectively, from the bounding *BglII* sites of the 13-kilobase *BglII* fragment. Other *BamHI* sites are 15.0 and 2.6 kilobases, respectively, outside these internal *BamHI* sites, as defined by the *BamHI* single digest fragments.

From these data, the distance predicted between the two *BamHI* sites within the 13-kilobase *BglII* fragment is 4.9 kilobases. We conclude that these *BamHI* sites generate the 5.0-kilobase fragment seen in the *BamHI* single digest, and that this fragment is sandwiched between the 15.0 and the 2.6 kilobase *BamHI* fragments (Fig. 2).

The 5.0-kilobase *BamHI* fragment has at its termini the only two *BamHI* sites which are present within the 13-kilobase *BglII* fragment. These must be the *BamHI* sites which are located within the two γ -globin genes (Table 2). The 5.0-kilobase *BamHI* fragment contains two 'half-genes' therefore (one to the 3' side and one to the 5' side of the intragenic *BamHI* site), and each of the other *BamHI* fragments contains one 'half-gene'.

It is possible to orientate the *BamHI* and *EcoRI* 'maps' with respect to the *BglII* sites by use of a *BamHI/EcoRI* double digest. We have shown that both the 2.6-kilobase *BamHI* and the 6.5-kilobase *EcoRI* fragments contain a *BglII* site. There are two possibilities: either the *BglII* site is the same in both the *EcoRI* and the *BamHI* fragments (as shown in Fig. 2), which predicts that the 6.5-kilobase *EcoRI* fragment will be cut by *BamHI* to yield a 2.6-kilobase double digest fragment. Alternatively, the 6.5-kilobase *EcoRI* and the 2.6-kilobase *BamHI* fragments are located at opposite ends of the 13-kilobase *BglII* fragment. In this case there would be no *BamHI* cut in the 6.5-kilobase *EcoRI* fragment (Fig. 2). The fact that a double digest with *BamHI/EcoRI* gives fragments of 2.6, 1.65, 1.05 and 0.65 kilobases, eliminates this second possibility.

The existence of four *EcoRI* fragments is compatible with two γ -globin genes. The *BglII/EcoRI* digest above locates an *EcoRI* site within one of these. The *BamHI* plus *EcoRI* digest locates the *EcoRI* site in the other γ -globin gene, and establishes that there are two γ -globin genes. The strongly hybridising 2.5-kilobase *EcoRI* fragment is cleaved by *BamHI* to give a 1.65-kilobase double digest fragment (Fig. 1); alternative possibilities are inconsistent with a *PstI/EcoRI* double digest (Fig. 3a).

The orientation of the 2.5-kilobase *EcoRI* fragment with respect to the *BamHI* sites is established by experiments with 3'- and 5'-specific probes (data not presented; see Fig. 4 legend). The 15-kilobase *BamHI* fragment does not hybridise with 5'-specific probes, whereas the 5.0-kilobase *BamHI* fragment and the 2.5-kilobase *EcoRI* fragment do. Hence the orientation of the 2.5-kilobase *EcoRI* fragment can only be that shown in Fig. 2. According to the *BamHI-EcoRI* map derived from these data, the 1.65-kilobase *EcoRI* fragment would be uncut by *BamHI* and would co-migrate with the 1.65-kilobase *BamHI + EcoRI* double digest fragment.

Therefore, the intragenic *BamHI* and *EcoRI* sites in both coding sequences are 800–1,000 base pairs apart. From the direct sequence known from the cDNA plasmids, it is known

Fig. 1 γ -Globin gene containing fragments generated by *EcoRI* (E), *BamHI* (B), *BglII* (Bg) and combinations of these enzymes. The calibration scale is in kilobase pairs and faint bands are marked by ●. 30 μ g of placental DNA, prepared according to ref. 10, was digested with the appropriate restriction endonuclease, denatured with alkali and electrophoresed on a 1.2% Agarose gel. The denatured DNA was transferred to a cellulose nitrate filter sheet by blotting¹², the filter cut into strips and hybridised with 50 ng per ml of ³²P-labelled pH γ G1, at 65 °C in 3 $\times$ SSC 0.1% SDS, for 2 d (SSC is 0.15 M NaCl, 0.015 M Na citrate pH 7.0). After hybridisation, strips were washed with 3 $\times$ SSC 0.1% SDS at 65 °C and finally with 0.1 $\times$ SSC 0.1% SDS also at 65 °C. Labelled components were then detected by autoradiography. All details of hybridisation and washing procedures and of the size markers used are as described in refs 14 and 15.

Fig. 2 Partial restriction site map of the γ -globin genes. Only approximate positions of the structural genes are shown. E, *EcoRI*; B, *BamHI*; Bg, *BglII*.

that the corresponding sites in the mRNAs are only 67 base pairs apart. This difference defines an intervening sequence (intron) between the *EcoRI* and the *BamHI* sites, at the same positions as those previously demonstrated in the rabbit and mouse β -globin genes and in the human δ and β -globin genes (refs 10, 11, 15, 19 and T. Maniatis, personal communication). The 1.05-kilobase *EcoRI*+*BamHI* double digest fragment is presumably generated from the intragenic *BamHI* and *EcoRI* sites flanking the large intron—the size of this fragment is in reasonable agreement with that predicted (0.85) from the map position of the *EcoRI* and *BamHI* sites described above. Figure 2 shows the map of the *BglII*, *BamHI* and *EcoRI* sites located by these experiments. (We will refer to the γ -globin genes as 'left' and 'right' as displayed in this figure.)

Cleavage of human DNA with *XbaI* gives three γ -globin gene fragments of 7.5, 5.0 and 3.7 kilobases (Fig. 3). A double digest with *BglII* yields fragments of 6.0, 5.0 and 2.25 kilobases. Thus, the 3.7-kilobase *XbaI* fragment is cleaved by *BglII*: this places an *XbaI* site 2.25 kilobases from the *BglII* site and a second *XbaI* site 3.7 kilobases away from this *XbaI* site. The 7.5-kilobase *XbaI* fragment is cleaved by *BglII* to give the 6.0-kilobase double digest fragment and this places an *XbaI* site 6.0 kilobases from the second *BglII* site. To orientate the *XbaI* sites with respect to the *BamHI* sites and within the *BglII* fragment, *XbaI* plus *BamHI* double digests were carried out. This yields the 7.5-kilobase *XbaI* fragment, the 5.0-kilobase fragment present in both *BamHI* and *XbaI* digests and the 2.6-kilobase *BamHI* fragment (Fig. 3). As the 2.6-kilobase *BamHI* fragment is generated from the 3.7-kilobase *XbaI* fragment, this allows the orientation of the *XbaI* sites with respect to the *BglII* sites. The only possible explanation for the existence of the 5.0-kilobase *BamHI* plus *XbaI* double digest fragment is that the two *XbaI* sites within the *BglII* fragment are located very close to the

position of the two *BamHI* sites mapped above. As *XbaI* does not cleave the γ -globin cDNA, and as the *BamHI* sites considered here are within the coding sequence of both γ -globin genes, the *XbaI* sites must be present in the intron, between the *BamHI* and *EcoRI* sites in both γ genes.

PstI generates γ -globin gene fragments of 5.0, 4.0 and 0.9 kilobases and a faint band of about 10 kilobases (Fig. 3). The *PstI* sites have been mapped in a double digest of *PstI* with *BglII*, *EcoRI* or *XbaI*. Cleavage of human DNA with *PstI* plus *BglII* gives γ -gene fragments of 5.0 and 0.9 kilobases (present in the *PstI* digest) and a double digest fragment of 2.2 kilobases (Fig. 3). This fragment must be derived from the 4.0-kilobase *PstI* fragment by *BglII* cleavage which places a *PstI* site 2.2 kilobases from a *BglII* site and also a *PstI* site 4.0 kilobases away from this *PstI* site. The *PstI* and *XbaI* double digest orientates the *PstI* sites within the *BglII* fragment: fragments of 5.0, 3.7 and 0.9 kilobases are obtained (Fig. 3) showing that the 4-kilobase *PstI* fragment contains the 3.7-kilobase *XbaI* fragment. A 5.0-kilobase fragment is present in both *PstI*, *XbaI* and *PstI*+*XbaI* digests which suggests that the *PstI* and *XbaI* sites which generate these 5-kilobase fragments must map near to each other. This is confirmed by the fact that one of the *PstI* sites, located above using *PstI* plus *BglII* double digests, maps very close to an *XbaI* site, independently located using a double digest with *BglII*, which defines one end of the 5.0-kilobase *XbaI* fragment. The 4.0 and 5.0 kilobase fragments are therefore contiguous on the DNA at a single *PstI* site. The position of the 0.9-kilobase *PstI* fragment will be discussed below.

Orientation of the physical map

To orientate the physical map with respect to the direction of transcription it is necessary to determine the orientation of the structural gene sequence. We have done this by hybridising restriction endonuclease digests to separate probes for the DNA regions to the 5' or 3' side of the intragenic *EcoRI* site. Plasmid pH γ G1 was cut with a mixture of *EcoRI* and *HindIII* restriction endonucleases: this gives two fragments of about 4 and 10 kilobases containing the γ -globin gene sequence to the 3' and 5' side of the *EcoRI* site, respectively. The two fragments were purified by gel electrophoresis, recovered from the gel²⁰ and labelled with ³²P by nick translation.

Filters carrying *EcoRI*-digested human DNA were hybridised with 3'- and 5'-specific probes. The 5' probe detected only the 6.5 and 2.5 kilobase fragments whereas the 3' probe detected the 1.6 and 0.65 kilobase fragments (Fig. 4).

Similar experiments (not presented) indicated that the 15-kilobase *BamHI* fragment contains only 3' information. This, combined with the fact that the 2.5-kilobase *EcoRI* fragment is only 5' containing, indicates that the orientation of the 2.5-kilobase *EcoRI* site with respect to the *BamHI* site in the right hand γ -gene can only be that shown in Fig. 2.

Localisation of the 3' *EcoRI* fragments

The mapping data described above do not allow us to locate the 1.65 and 0.65 kilobase *EcoRI* fragments. As both fragments contain DNA sequences to the 3' side of the *EcoRI* site in the γ -globin genes we anticipated that one fragment must be derived from the γ gene, and one from the α gene. To assign the *EcoRI* fragments to the γ genes we performed a *PstI* and *EcoRI* double digest. The α gene has a *PstI* site at position 136 and *PstI* should therefore cut the 3' *EcoRI* fragment of this gene whereas the γ gene has no such site. Strongly hybridising fragments of 4.0 and 1.8 kilobases, together with a fainter band at 1.6 kilobases were seen in this digest (Fig. 3). The 4.0 and 1.8 kilobase bands contain the 5' regions of the gene to the left and right in the map in Fig. 2, up to the *PstI* sites in each respective intron. The size of these fragments fits exactly with the map deduced in the preceding sections. The 1.6-kilobase band is the size expected for the 3' *EcoRI* fragment uncut by *PstI*. This fragment therefore must lie within the 5-kilobase *PstI* fragment and adjoin the 6.5-kilobase *EcoRI* fragment of the left hand

Fig. 3 a, γ -globin gene containing fragments generated by *PstI* (P), *XbaI* (X), *BglII* (Bg) and *EcoRI* (E) in single and double digests. Sizes are in kilobases. The position of certain faint bands is marked ●. b, γ -globin gene containing fragments generated by *PstI* (P), *XbaI* (X) and *BamHI* (B) in selected single and double digests. Sizes are in kilobases. The arrow marks the position of the very faint 10-kilobase *PstI* fragment seen in some digests. Experimental conditions for both experiments are as in Fig. 1.

Fig. 4 The orientation of the γ -globin genes within the neighbouring DNA. 30 μ g of *EcoRI* digested DNA (E) or 30 μ g of *EcoRI*+*PstI* digested DNA (E+P) was alkali denatured and run on 1.2% Agarose gels and transferred to filters (as described in Fig. 1). Strips were then hybridised with ^{32} P-labelled 4-kilobase pH γ G1 *EcoRI*+*HindIII* fragment (3' specific) and the 10-kilobase *EcoRI*+*HindIII* fragment (5' specific), as described in Fig. 1. In each case a threefold excess of unlabelled fragment of the opposite specificity is included in the hybridisation to reduce cross hybridisation due to probe contamination¹⁴. The running position of each size fragment is indicated.

γ -gene. The 0.65-kilobase *EcoRI* fragment cannot be seen clearly in the digest. The *PstI*/*EcoRI* digest was hybridised with a specific probe for the regions of the γ -gene to the 3' side of the intragenic *EcoRI* site (as described above in Fig. 4) to confirm these assignments. The 1.6-kilobase fragment is visible (Fig. 4) whereas the 0.65-kilobase fragment cannot be seen. (Compare with the *EcoRI* digests in Fig. 4 where both the 1.6-kilobase fragment and the 0.65-kilobase *EcoRI* fragment are clearly visible.) The 0.65-kilobase *EcoRI* fragment is cut by *PstI*, (presumably) at the region coding for amino acids 135–136–137 of the γ -globin polypeptide chain (see Table 1) which should remove 45 base pairs of DNA homologous to our probe. The remaining 100 base pairs should however be detected by the γ -probe. We have shown that this is the 3' end of the γ -gene and the failure to detect this 100-base pair fragment may be the result of low homology between the 3' region of the γ -gene and the γ -cDNA probe in use here (data not presented). A similar problem arose in our study of the δ - β -locus¹⁰ where we could detect the 3' regions of the δ -globin gene with β -globin cDNA sequences only with difficulty.

Finally, the *PstI* cleavage of the 0.65-kilobase *EcoRI* fragment explains the 0.9-kilobase *PstI* fragment. This fragment is derived from the γ -gene and extends from the *PstI* site in the intervening sequence of the gene to the *PstI* site at the DNA coding position for 136 of the γ -globin chain. We predict that a fourth *PstI* fragment containing the regions to the 3' side of the DNA coding for amino acid 137, should also be visible. This is seen as a very faint 10-kilobase fragment in some *PstI* digests (see Fig. 3, for example). As discussed above, we believe that this fragment is difficult to see for three reasons: it does not cross react well with our γ -probe, it contains only 100 base pairs of DNA homologous to our probe and it is large.

The arguments presented here show that the leftward γ -gene in Fig. 2 is γ -gene and the rightward gene is γ -gene. We have not shown that the 3' *EcoRI* fragments are contiguous with their respective 5' fragment at the intragenic *EcoRI* sites of the γ -genes. This could most simply be achieved by use of γ -globin chain mutants which have lost the *EcoRI* site, but these mutants are extremely rare^{1,2,22}. For the γ -gene, non-contiguity of the 2.5 and the 0.65 kilobase *EcoRI* fragments implies that a second *PstI* site must occur exactly 0.9 kilobases from both the *PstI* site close to the *BamHI* site, and the intragenic *PstI* site. Similarly, the γ -gene cannot contain more than an additional 0.75 kilobases of DNA, as this is all the DNA that is not included in gene-containing

fragments between the two γ -globin genes. We believe, therefore, that it is reasonable to assume contiguity of fragment round the intragenic *EcoRI* sites.

All the restriction site information derived above can be combined into the single map in Fig. 5a. We believe that this is the simplest map compatible with our data; other more complicated maps are not excluded, however. For example, the difficulty of detecting small fragments containing only short regions of structural genes makes it hard to eliminate the possibility that additional *EcoRI* sites are present (within an additional intron?) in the 3' regions of the two genes. We believe that this is unlikely for the same reasons discussed for the contiguity of the *EcoRI* fragments around the intragenic *EcoRI* sites. Molecular cloning of this locus will ultimately resolve this problem.

The major features of the map, shown in Fig. 5b, are as follows. We identify the γ -gene by the presence of the *PstI* site to the 3' side of the intragenic *EcoRI* site. The γ -gene is proved to be to the 3' side of the γ -gene as predicted previously from genetic evidence^{3,22}. Both genes contain introns between the *BamHI* sites (at position coding for amino acids 99–100) and the *EcoRI* site (at positions 121–122). These introns are approximately 800–1,000 base pairs in length, similar to those found in the human δ - and β -globin genes. Similar sequences in the same position have previously been found in mouse¹⁹ and rabbit β -globin genes¹⁵. The two γ -globin genes are separated by 3.5 kilobases of DNA, as compared with approximately 7.0 kilobases of DNA separating the human δ - and β -globin genes¹⁰ and the map spans 25.5 kilobases of DNA.

Several more general conclusions can be drawn. Our data are consistent with the presence of only two γ -globin genes; for more to be present, a reduplication of an entire region of DNA greater than 25 kilobases in length and sufficiently conserved to retain identical restriction sites over this length would be

Fig. 5 a, Physical map of the linked γ - and γ -genes. The position of the coding sequences are indicated by filled boxes. It should be stressed that only those restriction sites that generate fragments containing a portion of coding sequence are detected in these experiments. The coding sequences are shown as two blocks. There is no evidence to exclude the possibility that these blocks might contain further short introns. E, *EcoRI*; B, *BamHI*; Bg, *BglI*; P, *PstI*; X, *XbaI*. b, The major features of the human fetal globin gene locus.

required. In the individuals examined (from persons of English, Dutch and Welsh parentage) there is no demonstrable third γ -gene; therefore it is likely that the gene for HbF_{Sardinia} is an allele of one of the two γ -globin genes or that there is a polymorphism of γ -gene number in humans. We did not determine whether HbF_{Sardinia} was expressed in cord blood in these individuals and therefore final determination of the γ -globin gene must await investigation of a person who definitely synthesises this chain. In the small number of DNA samples used, no polymorphisms in the restriction fragment patterns were seen.

The demonstration of close linkage of γ - and γ -genes enables us to exclude one of the two models for the organisation of the

β -related globin gene family locus in humans. The existence of the fusion globins, Hb Lepore, where the N-terminal protein sequence of the δ -globin chain is fused to the C-terminal sequence of the β -globin chain²³, and Hb Kenya²⁵ where the N-terminal protein sequence of γ is fused to the C-terminal sequence of β -globin, had shown that the gene order must be either $\alpha\gamma\beta$ or $\alpha\beta\gamma$. We have demonstrated that the former is correct.

Infrared observations of the X-ray quasars 0241+622 and MR2251-178

TWO new quasars have recently been found through X-ray observations (the only other one being 3C273, see refs 1; 2). Ricker *et al.*³ have reported observations confirming the identification of the X-ray source 2251-178 with a quasar of visual magnitude 14.1. Canizares, McClintock, and Ricker⁴ have reported visual spectrophotometric observations of this quasar, and find its visual spectrum is much like other low redshift quasars. Apparao *et al.*⁵ have reported the discovery of a low redshift quasar identified with the X-ray source 4U0241+61. Margon and Kwitter⁶ have reported detailed visual spectrophotometry of this quasar, 0241+622, and likewise find that its spectrum is typical of low redshift quasars. Because of the importance of establishing any morphologically unique characteristics of X-ray quasars, these quasars should be observed at all possible wavelengths. We report here IR observations of the two newly discovered X-ray quasars. These observations indicate that the X-ray quasars have IR properties typical of low redshift quasars, and, along with 3C273, are among the brightest known quasars at IR wavelengths.

All observations reported here of 4U0241+622 and MR2251-178 were obtained on the 5 m Hale telescope on Palomar Mountain. Broadband photometry from 1.25 to 20 μ m of 0241+622 was obtained on 26 March 1978 UT and again on 20 July 1978 UT. Photometry from 1.25 to 10 μ m was obtained of MR2251-178 on 17 July 1978 UT and 20 July 1978 UT. These data are plotted in Fig. 1 along with the flux observed from 3C273 (ref. 7).

Spectrophotometric observations of 0241+622 from 1.5 to 2.5 μ m with a resolution $\Delta\lambda/\lambda \sim 0.05$ using a cryogenically cooled circular variable filter wheel spectrometer were obtained on 26 March 1978 UT; these observations were repeated on 20 July 1978 UT with a circular variable filter wheel of resolution

Fig. 1 The IR and visual energy distributions of the quasars 0241+622, MR2251-178, and 3C273 plotted against frequency. The data for 3C273 (+) is from ref. 7, the optical data for 0241+622 (●) is from ref. 6 and the optical data for MR2251-178 (x) is from ref. 4. ○ represent the de-reddened energy distribution of 0241+622, assuming $A_v = 4.6$ mag.

$\Delta\lambda/\lambda \sim 0.01$. Both sets of observations are shown in Fig. 2. The data were calibrated and corrected for atmospheric extinction using observations of the nearby B2Ia star 10 Persei. The data suggest that $P\alpha$ emission redshifted to $1.956 \mu\text{m}$ is present, but the atmospheric extinction limits the accuracy of the determination of the line flux of $P\alpha$.

Before the IR energy distributions of these quasars can be compared, the observed flux from 0241+622 must be corrected for significant galactic foreground extinction. Margon and Kwitter⁶ adopt a value of visual extinction $A_v \sim 4.6$ mag based on five separate estimates of the extinction. The present broad-band observations give an additional estimate of the extinction. For 10 quasars with redshifts $z \leq 0.2$, Neugebauer *et al.*⁷ find that the mean V ($2.2 \mu\text{m}$) = 3.1 mag with a spread of ± 0.4 mag. The observed V ($2.2 \mu\text{m}$) colour of 0241+622 is 6.7 mag if the flux did not vary between the times of the visual and IR observations. If the intrinsic V ($2.2 \mu\text{m}$) colour of 0241+622 is 3.1 ± 0.4 mag, the quasar thus suffers 3.6 ± 0.5 mag of differential extinction between $0.5 \mu\text{m}$ and $2.2 \mu\text{m}$. If a standard Van de Hulst number 15 reddening curve^{8,9} is applied, this implies $A_v = 4.0 \pm 0.6$ mag, consistent with the value adopted by Margon and Kwitter.

A further, though weak check on the extinction is obtained from consideration of the $P\alpha$ line flux. The flux in the $P\alpha$ line based on the data in Fig. 2, is $3 \times 10^{-16} \text{ W m}^{-2}$; the determination is uncertain because of the difficulty in determining the true continuum and in assessing the line flux shortwards of $1.96 \mu\text{m}$. The $H\beta$ flux as measured by Margon and Kwitter is $\sim 4.5 \times 10^{-17} \text{ W m}^{-2}$, giving a ratio $P\alpha/H\beta \sim 7$. The observed ratio $P\alpha/H\beta$ in 3C273 is 0.3 (refs 10, 11), in agreement with theoretical calculations if the region is optically thick to Lyman series photons¹². If 0.3 is the intrinsic value of $P\alpha/H\beta$ and if the normal reddening curve applies, a visual extinction $A_v = 3.2$ mag is implied. In view of the large uncertainty in the $P\alpha$ line flux and in the intrinsic $P\alpha/H\beta$ ratio, we consider the agreement with other determinations of A_v acceptable.

The de-reddened IR energy distribution of 0241+622, based on $A_v \sim 4.6$ mag, is shown in Fig. 1. For wavelengths $\leq 10 \mu\text{m}$ the energy distributions of all three quasars are remarkably similar and in this case cannot be distinguished from other low

Fig. 2 The near-IR spectrum of 0241+622, plotted against wavelength. ● represent data obtained with a spectral resolution of $\Delta\lambda/\lambda \sim 0.05$, while + represent data obtained with a spectral resolution of $\Delta\lambda/\lambda \sim 0.01$.

Table 1 Emitted power per fractional bandwidth (νF_ν)

Wavelength	0241+622	2251-178	3C273
$2 \mu\text{m}$	12	4.7	120
$0.5 \mu\text{m}$	30	4.0	160
$2.2 \text{ \AA}$ (5.5 keV)	2	1-9	10-50

Values are in units of 10^{37} W . The visual and IR data for 3C273 are from ref. 7, while the X-ray data for all these quasars are from ref. 5; the visual data for 0241+622 are from ref. 6; the visual data for MR2251-178 are from ref. 4.

redshift quasars. For a sample of eight low redshift quasars ($z \leq 0.2$) studied by Neugebauer *et al.*⁷, the average $2-10 \mu\text{m}$ spectral index α ($f_\nu \propto \nu^\alpha$) is -1.1 with a total spread of ± 0.3 . The intrinsic $2-10 \mu\text{m}$ index of 0241+622 is 0.9, while that of 2251-178 is 1.0. Both of these are thus well within the range of indices of the sources studied by Neugebauer *et al.*

It is of interest to compare the observed IR, visual, and X-ray luminosities of 0241+622, 2251-178, and 3C273. Table 1 shows the power per fractional bandwidth, νF_ν , where ν is the rest frequency and F_ν is the emitted power density, for the X-ray, visible and IR wavelengths; the Hubble constant has been taken as $50 \text{ km s}^{-1} \text{ mpc}^{-1}$. These observations do not show a strong correlation between the IR, visual, and X-ray luminosities of these quasars, although to within factors of three the ratios of IR, visual, and X-ray luminosities are similar for all three quasars. Note, however, that the X-ray flux for 3C273 has varied by a factor of 5 over a 2-yr period¹³ while the visible and IR fluxes have remained essentially constant (see ref. 7); this suggests that there is no direct link between the X-ray and visual/IR emission mechanisms.

The main distinguishing feature of these quasars at IR wavelengths is their brightness. The three currently known X-ray emitting quasars are comparable in visual brightness to the brightest quasars in the compilation of Burbidge, Crowne, and Smith¹⁴ and are the three brightest observed quasars at $2.2 \mu\text{m}$ (see ref. 7). The fact that the three quasars which are known to be X-ray sources are among the brightest quasars in the optical wavelengths supports the suggestion of Ward *et al.*¹⁵ and Canizares, McClintock, and Ricker⁴, that all quasars are relatively bright X-ray emitters, and sensitive X-ray surveys should provide a powerful tool for the discovery of new quasars.

We thank G. Tuton and J. Carrasco for assistance with the observations. We also thank B. Margon for sending a preprint of his observations of 0241+622. This research was supported by NSF grant AST 77-20516 and NASA grant NGL 05-002-207.

Infrared observations of the black-hole candidate V861 Sco

V861 Sco was found to be an eclipsing binary by Cousins and Lagerwey¹ and its radial velocity curve has been determined by Walker². The primary is a B01 star, and taking suitable values for its mass the radial velocity curve suggests the unidentified secondary has a mass in the range 5–12 $M_{\odot}$. Recently Polidan *et al.*^{3,4} showed that the system may be an X-ray source; it is therefore a black-hole candidate. We therefore thought that observations at other wavelengths would be of interest and we report here IR observations from 1.2 to 3.6 μm .

V861 Sco was observed from 25 July to 17 August 1978 at the Cabezon observatory, Tenerife, with the 1.5 m IR flux collector. The observations were made with the Leicester University and Royal Edinburgh Observatory IR photometers, both of which are of conventional design, use InSb detectors, and have identical interference filters. Each observation is the average of a number of 20 s integrations. The error bars for our data shown in Fig. 1 are the standard error of the mean found from these integrations. V861 Sco is very low on the southern horizon from Tenerife, and can therefore only be observed once each night.

The standard used was SAO227504 which is less than 0.5° from V861 Sco. This standard was in turn calibrated against α Cyg ($J = 1.00$, $K = 0.89$, $L = 0.78$, Johnson⁵), which was just rising at the time of observation of V861 Sco, and subsequent observations of α Cyg allows a correction for atmospheric extinction to be made. This procedure gives rise to a light curve of very reliable shape but whose absolute calibration has errors of ± 0.1 magnitudes.

The ephemeris used is calculated from the data of Cousins and Lagerwey¹ and gives the primary minimum a phase of zero.

$$\phi = (\text{JD} - 2440493.236) \times 0.127418 - 0.123$$

We have not used the ephemeris quoted by Cousins and Lagerwey¹ as this uses an epoch of JD = 2430000 which exaggerates any errors in the period. As can be seen from our data and the error in the period, this ephemeris is quite adequate at present and does not need clarifying as suggested by Polidan *et al.*⁴. Furthermore, this ephemeris places Polidan's possible X-ray eclipse at about primary minimum, when the secondary is in front of the B01a primary, which is not very satisfactory.

Fig. 1 Light curves of V861 Sco: a, 1.2 μm ; b, 2.2 μm . ●, Our magnitudes, ×, magnitudes from Tanzi *et al.*⁶.

Table 1 IR eclipse depths and optical data of the secondary minimum

	U	B	V	J	K
Δm_1	0.31	0.27	0.27	0.27	0.33
Δm_2	0.19	0.19	0.19	0.08	0.10
B_2/B_1	0.65	0.73	0.73	0.32	0.34
A_2/A_1	0.30	0.26	0.26	0.24	0.29

Figure 1 shows our 1.2 and 2.2- μm light curves and also includes the IR data of Tanzi *et al.*⁶. Their data agrees well with ours at 2.2 μm but is about 0.1 mag fainter at 1.2 μm ; this is probably due to our error in the absolute calibration due to the large air-masses. Neither our data nor that of Tanzi *et al.*⁶ is of sufficient quality to draw a useful 3.6- μm light curve.

The main interest of these observations is the shallow IR secondary minimum. Table 1 shows our best estimate of the IR eclipse depths together with the optical data taken from Cousins and Lagerwey¹. The ratio of secondary to primary surface brightness, B_2/B_1 , is calculated from these depths. We have also calculated A_2/A_1 , the eclipsed area at either primary or secondary eclipse divided by the area of the primary, assuming the eclipse is total. If the eclipse is not total this column is a lower limit for A_2/A_1 .

The rapid decrease of the surface brightness of the secondary from the optical to the IR clearly shows that this object is non-stellar. For example, if we take -0.79 for the $V-K$ colour of the B01a primary, we can show the $V-K$ colour of the secondary is -1.71 which doesn't correspond to any known star.

The non-stellar secondary is probably a compact object surrounded by an accretion disk. In the IR the cool outer regions of the disk are optically thick to free-free radiation and a low surface brightness is observed. In the visible region of the spectrum, however, the outer regions of the disk would be optically thin, allowing the hotter central region to be observed.

The presence of an optically thin accretion disk is also supported by the emission lines seen by Walker² and Polidan *et al.*³.

It may be argued that we have taken the eclipse depths at face value and not made any allowance for gravity darkening, ellipticity or heating effects on the near side of the primary. These effects can be removed by 'rectifying' the light curve and this has been done by Walker⁷ for the optical data. If the main distortion to the light curve is the ellipticity of the primary this effect should be the same in both the visible and near IR. Thus we might apply Walker's rectification to the IR light curves but, as this has an amplitude of 0.15 mag, it would more than remove the secondary minimum. Walker's rectification may therefore be excessive.

Any rectification applied to the IR light curves will only make the ratio B_2/B_1 smaller still, so our conclusion that the secondary is non-stellar remains. The shallow IR secondary eclipse also means that the area of the primary seen at phase 0.25 cannot be more than 10% greater than the area seen at phase 0.5. This small ellipticity of the primary implies that it does not fill its Roche lobe. If the primary were to fill its Roche lobe a difference of 17% would be needed; this requirement is almost independent of the assumed mass ratio. Thus the photosphere does not apparently fill its Roche lobe; however, the likely extended atmosphere of the primary could give a substantial mass transfer through the inner lagrangian point. Alternatively, if we regard the mass transfer as being due to a stellar wind then the secondary must contain a compact object, which would have to be a black hole. This conclusion is independent of any assumption about the possible X rays.

It should also be noted that if, following Walker², we take $A_v = 1.47$ the whole system has a K excess of 0.4 mag. This cannot, of course, be due to the eclipsed radiation from the secondary. If the eclipses are partial, and the secondary is effectively larger at IR wavelengths this would give the IR excess. Alternatively the whole system may be surrounded by free-free emitting material.

We conclude that these observations support the idea that the secondary of V861 Sco contains a black hole. However, a more convincing identification of the X-ray source with V861 Sco is needed. Even if V861 Sco does not turn out to be an X-ray star it would still seem to be an interesting system. Either way the IR data should assist with any future models of the system.

We thank the SRC for travel funds to Tenerife. M.R.S. has an SRC studentship and A.B.G. has an SRC fellowship. We also thank A. J. Longmore and P. M. Williams of the Royal Observatory, Edinburgh, for their observations which allowed us to complete the light curves.

HEAO 1 observations of high-energy X rays from 3C273

THE first detection of high-energy (13–120 keV) X rays from the vicinity of the quasar 3C273 is reported here. This object is one of three quasars associated with X-ray sources^{1–3}. Low energy (2–10 keV) X rays^{3–5} and γ rays (50–500 MeV)⁶ have been previously observed.

The present observations were made with the 13–180 keV slat collimated detectors of the high energy X-ray and low energy γ -ray (A4) experiment on the HEAO 1 satellite⁷. These detectors each have areas of $\sim 100 \text{ cm}^2$ and fields of view of $\sim 1^\circ \times 20^\circ$ (FWHM). The narrow slats intersect on the +Y axis and are inclined with respect to the Y-Z plane of the satellite at angles of -30° (left slat) and $+30^\circ$ (right slat).

The A4 detectors were pointed at 3C273 for ~ 6 h on 30 June, ~ 8 h on 3 July, and ~ 10 h on 5 July 1978, resulting in a positive

detection. In addition, the source was observed for ~ 20 d during December 1977 and January 1978 in the scanning mode (satellite spinning). During each rotation of the satellite the source appears a maximum of ~ 10 s in the field of view; however, there was no detection of this source.

During the pointed observations the detectors were alternately directed at 3C273 and at a reference position $\sim 4^\circ$ from the quasar to obtain background data. Background data during the scanning observations were obtained from data adjacent to source crossings. Individual photon events were pulse height analysed in 64 channels from ~ 13 to ~ 180 keV and binned in five coarse energy bands from 13–25, 25–45, 45–85, 85–120, and >120 keV. Count rates in these bands were computed by averaging the background-subtracted data corrected for detector response, assuming a source at the position of 3C273 and using the Goddard Space Flight Center (GSFC) attitude solution. No data were used when the Earth or other known X-ray sources were in the field of view. A comparison of the GSFC attitude solution with the more accurate solution of the scanning modulation collimator (A3) experiment for several orbits indicated no significant (>5 arc min) differences. The hard X-ray source is localised to a region of $\sim 4.5 \text{ deg}^2$ which includes 3C273.

The results of the observations are summarised in Table 1. The June/July 1978 data show statistically significant fluxes independently in each detector of $\sim 8\sigma$, $\sim 6\sigma$, $\sim 4\sigma$, and $\sim 3\sigma$ in the four energy bands from 13 to 120 keV. The December 1977/January 1978 scanning data yield only an upper limit (our detection was only at 2σ level of confidence) combining all data from ~ 13 to ~ 120 keV. The ratio of the count rate in December 1977/January 1978 to the rate in June/July 1978 is 0.8 ± 0.5 . We note that the X-ray flux of 3C273 is variable on a time scale of months^{8–9} and that during our June/July 1978 observations 3C273 was in a high state⁹.

The count rate spectrum for the June/July 1978 observations is shown in Fig. 1a. Figure 1b shows the inferred photon spectrum, derived from detector efficiency curves determined by multiple scans over the Crab Nebula. Previous measurements at lower X-ray energies² and at γ -ray energies⁶ are also included for comparison. The combined Ariel V and HEAO A4 data (in the region of 15 keV) indicate variability. The HEAO A4 data taken alone are consistent with a single power law photon spectrum with spectral index $\gamma = 1.67 \pm 0.14$ (1σ error). If we include the COS B data in the fit the spectral index is 2.05 ± 0.03 (1σ error).

The HEAO 1 cosmic X-ray (A2) experiment and the COS B experiment also observed 3C273 during June and July 1978 (not shown in Fig. 1). The COS B data (50–500 MeV) are consistent with their measurements in June 1976 but an intensity decrease

Fig. 1a HEAO A4 count rate spectrum for the June/July 78 observations. Only left slat detector data are shown. Errors are $\pm 1\sigma$ and include estimates of systematic errors due to background variations. Upper limits are at a 2σ confidence level. **b**, Photon spectrum from 1 keV to 500 MeV (see text for refs). HEAO A4 spectral points are obtained by combining left slat and right slat data. Errors are $\pm 1\sigma$ and include estimates for the uncertainty in converting from counts to photons.

by as much as a factor of 2 cannot be excluded (Swanenburg, personal communication). The A2 data (2–60 keV) agree well with the A4 observations at 20 keV but indicate a flatter spectrum at lower energies. No single power law spectrum in the range 2–60 keV yields a satisfactory fit to the A2 data. However, if a fit to a single power law is forced, the fit yields a spectral index of ~ 1.4 (ref. 10).

A comparison of our data with those at lower X-ray energies and higher γ -ray energies indicates that there is an overall trend for spectral steepening from low to high energies with perhaps a break near ~ 20 keV. It is possible that the high energy γ -rays do not originate from the same region as the X rays¹¹. This should be considered in any comparison of spectral data in the X-ray and γ -ray regions.

We thank Dr Alan Levine for useful discussions and Peter Byrne for help in the data analysis, and Maureen Conroy and the HEAO 1 A3 group for providing attitude solutions during the June/July 1978 observations. This work was partially supported under NASA grants NAS8-27974 and NAS8-27975.

Energy sources for X-ray cluster emission

SOME galactic clusters are strong X-ray emitters¹, and we consider here the problem of establishing certain models for the source of this radiation. In the first model we suppose that the X rays are thermal bremsstrahlung from a hot quasi-isothermal inter-cluster gas. Typical parameters for the temperature, particle density and total mass of the gas are² $T \sim 3 \times 10^8$ K, $n \sim 10^{-3}$, $M \sim 3 \times 10^{44}$ kg. If we assume³ relative nuclei solar abundances, then the thermal energy contained in the gas is $E_T \sim 2 \times 10^{64}$ erg. This is $\sim 10\%$ of the total rest mass energy of a $10^{11} M_\odot$ galaxy and clearly poses a problem for potential energy sources.

To check the necessity of having a 'current' energy source (light times away) one must consider the cooling rate of the gas and compare it with its estimated age. The essential kinetic energy loss is from free-free bremsstrahlung transitions and particle-ion inelastic collision which excite ion-electron levels. However, the above kinetic energy is so high, $1.5 kT \sim 40$ keV that few ions exist with many electrons. For example, Fe XXVI, the hydrogenic iron ion, is bound by only 9.2 keV. Taken together with the small number of heavy nuclei present at all, the latter cooling mechanism is completely negligible. For a constant density plasma then, the cooling rate is⁴

$$\frac{3}{2} nK \frac{dT}{dt} = 1.42 \times 10^{-27} n_e \sum_i n_i Z_i^2 \left(\frac{T}{K} \right)^{1/2} \text{ erg cm}^{-3} \text{ s}^{-1} \quad (1)$$

where n is the total number of free particles per cm³ and n_i is the density of nuclei of charge Z_i . We consider only electron-nucleus collisions as in the non relativistic approximation ($T \ll 6 \times 10^9$ K) the radiation from electron-electron collisions is much weaker⁵. Taking $n = 4.6 \times 10^{-3}$ cm⁻³ as a typical value with $n_{He} = 0.1 n_H$ the temperature falls according to

$$T(t) = \{T_0^{1/2} - 157.5t\}^2 \text{ K} \quad (2)$$

where t is in 10^9 yr and T_0 is the initial temperature in K. If we take $T_0 = 9 \times 10^8$ K then after 10^{10} yr the gas cools by only 10%. We conclude then that the hot gas may be very old, heated from its past with no current source necessary. We seek, therefore, energy sources within the cluster that were operating in the remote past and had short astronomical lifetimes with efficient energy production. The quasars are natural candidates. Due to their high intrinsic luminosities $\sim 10^{45}$ – 10^{48} erg s⁻¹, their lifetimes are necessarily short $\sim 10^8$ yr. As there are few quasars of small redshift (assumed cosmological) the quasar period of galactic evolution must be associated with young galaxies. One advantage of the quasar model is the following. If the heat input was too large, then the gas would no longer be gravitationally confined in the cluster. Instead it would envelop them. Abell clusters 399 and 401 may be examples of the overheating case⁶. Conversely, if the heat input was too small then the cluster

would not be an X-ray emitter at all. This would explain why some clusters have little or no X-ray emission. If we assume that the gas is at least as old as the galactic cluster we can estimate the age of the cluster in this model. Schmidt⁷ estimates that the space distribution of quasars is $10^{-6}(1+z)^6$ quasars Mpc^{-3} , where z is the redshift. This is valid up to $z \approx 2.5$. Assuming⁸ that the space density of galaxies is 0.03 galaxies Mpc^{-3} requires that the number of quasars relative to the number of galaxies at redshift z is $dN_{\text{rel}}/dz \approx 3 \times 10^{-5}(1+z)^6$. Thus we expect $4.3 \times 10^{-6}(1+z_0)^7$ relative number of quasars to have existed between $z = z_0$ and $z = 0$. If the energy per quasar which goes into heating the surrounding gas is R we deduce that the age of the cluster z_c in units of z is

$$z_c = (5.84) \left(\frac{E_T}{RS} \right)^{1/7} - 1 \quad (3)$$

where S is the number of galaxies in the cluster. Values of z greater than or less than z_c of equation (3) give a gas too hot or too cold than is observed. z_c depends weakly on the unknown number R . One may estimate this as follows. The only way that a completely ionised dilute intercluster gas can be effectively heated to such high temperatures is from collisional heating. Charged particles, cosmic rays, streaming out of quasars are the primary heating mechanisms in this model. According to Ipavach's analysis⁹ the maximum cosmic ray luminosity for a giant $10^{12} M_\odot$ galaxy is $10^{45} \text{ erg s}^{-1}$ for 10^8 yr yielding $3 \times 10^{62} \text{ erg}$. Taking into account that only a small percentage of the cosmic ray flux deposit their energy within the intercluster gas we estimate that a reasonable $R \sim 10^{61} \text{ erg}$.

We have applied the above analysis to Cluster Abell 2218. The parameters of this source have been given by Birkinshaw¹⁰. We take $T \sim 3 \times 10^8 \text{ K}$; $M_{\text{gas}} \sim 3 \times 10^{44} \text{ kg}$; $n \sim 4.6 \times 10^3 \text{ cm}^{-3}$; $S \sim 6.2 \times 10^4$. Then from equation (3)

$$z_c (\text{Abell 2218}) \approx 2.24 \quad (4)$$

This corresponds ($H = 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$) to an age of $16.2 \times 10^9 \text{ yr}$.

The second model that we consider is a specific realisation of Katz's suggestion¹¹ that the X-ray emissions are from many distinct 'galactic type' sources rather than from an all pervading hot intergalactic gas. According to Rees¹², the 2.7° microwave background is not attributed to the cooling of big bang primordial radiation but to a later $t \sim 10^6$ – 10^7 yr epoch of intense stellar nucleosynthesis and the observed ratio $N_\gamma/N_b \sim 10^8$ is naturally derived. An essential prediction of the Rees' cosmology is the appearance of dead remnants of massive stars strewn throughout the Universe, being the relics of the first few millennia. It seems reasonable that such objects could form large dead star clusters. In particular, one could imagine an extensive system composed of a black hole cluster with attendant matter in the form of captured gas and galaxies. This would then form the missing virial mass. A small percentage of the black holes would be in binary systems with a normal star, recently condensed out of the cluster medium. Taking $10^{37} \text{ erg s}^{-1}$ as the average X-ray luminosity of a black hole binary we would require $\sim 10^6$ – 10^8 binary systems within a cluster. If the black hole cluster is the virial mass defect then $10^{15 \pm 1} M_\odot$ per cluster is in the Rees' remnants: if each has an average mass of $100 M_\odot$ then only 10^{-8} – 10^{-4} of the available remnants need be in X-ray binary systems. Alternatively, the remnants may be supermassive and accreting matter from a diffuse uniform density ρ environment. The accretion rate is $\rho \pi R^2 v$. For rates 10^{-10} – $10^{-8} M_\odot \text{ yr}^{-1}$ (giving typical black hole luminosities) we require 10^4 – 10^5 black hole remnants with mass $M \sim 10^{11}$ – $10^{12} M_\odot$ for $\rho \sim 10^{-3} \text{ protons cm}^{-3}$. The interpretation then is that the extensive X-ray emission from galactic clusters is a physical manifestation following from the Rees' cosmology: this has a dramatic and testable prediction. Because of the rotating black hole sink, the accretion disks have a strong density gradient of optically thin to optically thick material¹³. Consequently the spectrum is expected to consist of a thermal bremsstrahlung low energy part from

the optically thick region and a high energy inverse Compton part from the optically thin region. The spectrum therefore should drop with a black body slope to $\leq 50 \text{ keV}$ and then begin to increase to a broad (comptonised) hump out to a few hundred keV. It would be desirable to have good X-ray data between the region 10–500 keV if X-ray cluster emission has this two component form.

Finally the two models discussed here may be unified. If the mysterious quasar source has its origin in gravitational collapse¹⁴ then a smaller black hole cluster may be the remnant of early quasar activity.

We thank Martin Rees and Dennis Ross for their comments. R.W.T. thanks the Ames Laboratory for hospitality. This work was supported by the US Department of Energy, Office of Energy Research, Division of High Energy and Nuclear Physics.

Auto-irradiation effects in DT pellets

FUSION reactors based on magnetic containment and operating in a quasi steady-state will need to be refuelled during their burn period. The ballistic injection of solid pellets of hydrogen isotopes, first suggested in 1954¹, still seems to be the most promising method, and two satisfactory techniques for fabricating solid hydrogen pellets have been developed. In one, a continuous extrusion of solid hydrogen is thermally chopped into cylindrical pellets². In the other, a jet of liquid hydrogen is acoustically broken into uniform droplets which are then frozen by reducing the pressure to below the triple point value³. Both techniques have worked well with deuterium, but fusion reactors will need DT pellets, and we consider here how the radioactivity of tritium will affect the situation. Two effects are apparent with characteristic times which may be short enough to be of practical significance: thermal stress arising from the deposition of decay heat throughout the pellet and electric stress caused by the charging of the pellet due to the escape of β particles from its surface. For a pellet of radius a , the thermal stress varies as a^2 and the electric stress as a^{-2} , which leads to both upper and lower size limits at radii where the effective stress approaches the yield stress of solid hydrogen. Fortunately the range of pellet radii envisaged in current reactor concepts (10^{-2} – 10^{-4} m) falls mid-way between the two limits.

The heat produced by the β decay of tritium in an equimolar DT mixture is 1.0 W mol^{-1} . In a thermally insulated sample this would cause a uniform temperature rise, but in pellets prepared by the techniques mentioned and injected into a cold vacuum chamber, there will be radial temperature gradients caused by

Fig. 1 Variation of equilibrium temperatures with pellet size. The solid curves are the central temperatures for cylindrical (C) and spherical (S) pellets. The dashed curve is the surface temperature. The triple point temperature of DT is 19.8 K.

outward heat flow. This can happen during extrusion by conduction through the nozzle; in isolated pellets evaporation establishes an equilibrium surface temperature which increases with pellet radius. By equating evaporative loss with decay heat we find this to be 7.0–8.7 K for the size range quoted above; radiative heat transfer is negligible in these conditions. To arrive at the equilibrium radial temperature distribution we assume the pellets to have constant surface temperature T_s and uniform heat generation A_0 , and a thermal conductivity K which varies with temperature. This leads to a parabolic distribution of the form:

$$\int_{T_s}^{T_c} K dT = \frac{A_0}{C}(a^2 - r^2)$$

where the numerical factor C is 4 for a cylinder and 6 for a sphere⁴.

The thermal conductivity of solid DT is unknown, but it has been suggested that when freshly frozen it may behave like 72% para H_2 (ref. 5). The variation of central temperature with pellet size shown in Fig. 1 is calculated on this assumption, and suggests that pellets smaller than about 2 cm radius are unlikely to have molten centres.

The thermal stress at the surface of a pellet whose temperature is a function only of radius is proportional to the mean temperature minus the surface temperature⁶, that is

$$(\sigma)_s = \frac{\alpha E}{(1-\nu)}\{\bar{T} - T_s\}$$

where α is the linear expansion coefficient, E is Young's modulus and ν is Poisson's ratio. By averaging the parabolic temperature distribution we find the equilibrium surface stress to be:

$$(\sigma)_s = \frac{\alpha E}{(1-\nu)} \cdot \frac{A_0 a^2}{DK}$$

where the numerical factor D is 8 for a cylinder and 15 for a sphere. The growth rate of this stress is a function of the dimensionless quantity $\kappa t/a^2$, where κ is the thermal diffusivity; the time t to reach 75% of the equilibrium stress is $0.25a^2/\kappa$ for a cylinder and $0.16a^2/\kappa$ for a sphere⁴.

There are no published experimental data on the mechanical or thermal properties of DT, so to estimate the surface stress and

Table 1 Data for thermal stress calculation

Quantity	Unit	$T = 5$ K	$T = 10$ K	Material	Ref.
B_s	$\text{mol m}^{-3} \text{K}^{-3}$	0.26	0.26	DT	5
H	W mol^{-1}	1.0	1.0	DT	
αA_0	$\text{W m}^{-3} \text{K}^{-1}$	6.6	26	DT	
K	$\text{W m}^{-1} \text{K}^{-1}$	0.2	0.8	nH_2	5
$(1-\nu)$		0.7	0.7	nD_2	7
E	MN m^{-2}	460	420	D_2	8
κ	$\text{cm}^2 \text{s}^{-1}$	0.14	0.083	nD_2	9
Stress					
cylinder	GN m^{-2}	$2.7a^2$	$2.4a^2$		
sphere	GN m^{-2}	$1.4a^2$	$1.3a^2$		
(t)_{75%}					
cylinder	10^4 s	$1.8a^2$	$3.0a^2$		
sphere	10^4 s	$1.2a^2$	$1.9a^2$		

To evaluate the stress we note that the solid density of hydrogen closely obeys the empirical relationship⁵ $(\rho_s)_T = (\rho_s)_0 - B_s T^3 \text{ mol m}^{-3}$, whence $\alpha = B_s T^2 / \rho_s$. As $A_0 = H\rho_s$, we have $\alpha A_0 = HB_s T^2$.

its growth rate we have used a judicious mixture of measured data for other solid combinations of the hydrogen isotopes together with some predictions for DT based on them. The values used to plot the graphs in Fig. 2 are given with their sources in Table 1.

Electrical stress on isolated pellets arises from charging due to the escape of β particles born sufficiently near the surface and having outwardly directed velocities. The electrostatic energy of a sphere with a surface charge Q is $\mathcal{E} = Q^2/8\pi\epsilon_0 a$ and hence the outward electrostatic pressure at the surface is

$$P = -\frac{d\mathcal{E}}{dv} = \frac{Q^2}{32\pi^2\epsilon_0 a^4}$$

If its radius a is small enough, a pellet will charge up to a value Q_{crit} beyond which disruption occurs; we suggest that the critical pressure at this point can be identified with the yield stress. It is

Fig. 2 Stress in DT pellets. The solid sloping lines show the steady state electrical and thermal stresses. The broken lines show the times to reach 75% of these stresses. (C) refers to cylindrical pellets, (S) to spherical. The pellet surface temperature is 5 K. The horizontal lines are measured yield stresses for polycrystalline hydrogen.

analogous to the Rayleigh stability criterion for charged liquid droplets¹⁰, which can be written:

$$\gamma \geq Q^2/64\pi^2\epsilon_0 a^3$$

where γ is the surface tension. If pellets behave like droplets, we may expect further charging to expel from the surface small fragments carrying sufficient charge to restore the stability criterion $Q \leq Q_{\text{crit}}$. For sufficiently large radii Q_{crit} will not be reached, as it would imply a potential greater than that corresponding to the maximum β energy ($V_{\text{max}} = 18$ keV); such pellets will be electrostatically stable.

The rate of charging is $dQ/dt = e(dn/dt)$, where dn/dt is the electron loss rate from the surface. It has the initial value:

$$\left(\frac{dn}{dt}\right)_0 = 4\pi a^2 RS$$

where R is the thickness of a hypothetical layer from which all β particles are thought to escape and S is the activity. As the potential of pellets of all radii rises towards V_{max} asymptotically, it is convenient to make quantitative assessments in terms of their potential V . Using the relationship $Q = 4\pi\epsilon_0 a V$, we have:

$$\left(\frac{dV}{dt}\right)_0 = eaRS/\epsilon_0$$

which we evaluate by taking R to be approximately the half-range for self absorption in tritium, quoted by Evans¹² as 0.039 mg cm^{-2} ; the value of S for an equimolar DT mixture is $2.13 \times 10^{17} \text{ decays kg}^{-1} \text{ s}^{-1}$. This gives:

$$\left(\frac{dV}{dt}\right)_0 = 1.5 \times 10^6 \text{ a V s}^{-1}$$

The time taken to charge to a given fraction of V_{max} will depend on the β energy spectrum, but we consider it sufficiently accurate for these estimates to assume it to be flat, so that:

$$V = V_{\text{max}} \left\{ 1 - \exp \left[- \left(\frac{dV}{dt} \right)_0 t / V_{\text{max}} \right] \right\}$$

Figure 2 shows the equilibrium electric stress,

$$P_{\text{max}} = \epsilon_0 V_{\text{max}}^2 / 2a^2 = 1.4 \times 10^{-3} / a^2 \text{ N m}^{-2}$$

and the charging time to 75% of P_{max} ,

$$(t)_{75\%} = 2.4 \times 10^{-2} / a \text{ s}$$

to facilitate direct comparison with the thermal stress.

In assessing our results the first point is that the total stress is a minimum for pellets of ~ 1 mm radius. This is a convenient size for fusion reactor concepts¹³; a total injection rate of 100 pellets per second would give a gross output of about 4,000 MW(th) at 10% burn-up per pass.

In the absence of data on the strength of solid DT, the measured yield stresses for polycrystalline H_2 and D_2 ⁸ are shown in Fig. 2. Using these figures as a guide, we see that pellets smaller than 10^{-2} m radius are unlikely to suffer early disruption due to thermal stress. Larger pellets may need to be fabricated and used within a few seconds, otherwise they may be prone to surface cracking and central melting, both of which could increase their ablation rate on entering a hot plasma. Electric stress seems to be of little consequence unless pellets are smaller than 10^{-4} m radius, where the slow charging rate will diminish its practical importance.

Mercury(II) sulphide: a photo-stable semiconductor

THERE is much interest in photo-electrochemical cells which use a semiconductor-electrolyte junction to transduce light into electrical and chemical energy¹. The semiconductors investigated to date fall into two main groups, the first of which contains photostable material but which shows response in the UV rather than the visible region of the spectrum, for example, n-titanium dioxide², n-strontium titanate³, n-potassium tantalate⁴, n-tin oxide⁵ and n-barium titanate⁶. The second group comprises compounds which respond to the visible region of the spectrum but are photochemically unstable such as n-gallium phosphide⁷, n-indium phosphide⁸, n-cadmium sulphide⁹, and n-cadmium selenide¹⁰. Attempts have been made to extend the spectral response of the materials belonging to the first group, by doping¹¹ and chemically affixing dyes to the surface of the semiconductor¹². Some success has been attained in stabilising some of the members of the second group; for example, cadmium sulphide and selenide are stable in polychalcogenide solutions¹³. If cells containing a semiconductor-electrolyte junction are to be of any practical use in the harnessing of solar energy then the following criteria for the semiconductor should be met: (1) they should absorb visible radiation; and (2) be photostable and capable of use in powder form. Clearly, if the conduction and valence bands of the semiconductor have energies that facilitate proton reduction and oxidation of hydroxyl ions respectively this would be an added bonus as the cells could be used to either photo-assist or photo-electrolyse the water¹⁴. We report here on mercury(II) sulphide (cinnabar) band gap = 2.1 eV¹⁵ which fulfils most of the above criteria¹⁶.

Fig. 1 Plot of potential versus time for red HgS in pH 7 (unbuffered) 0.1 M NaNO_3 , with respect to an SCE.

Fig. 2 Plot of current versus time for HgS (held at 0 V versus SCE) in pH 7 (unbuffered) 0.1 M NaNO₃. Solid line, untreated red HgS. Dashed line, red HgS, blackened by irradiation in potassium iodide. Effective area of electrode irradiated is 2.25 cm² and light intensity is $\sim 2.5 \times 10^{-2}$ W cm⁻².

The electrodes consist of a platinum mesh coated with cinnabar (optoacoustic spectra show that the samples absorb little radiation above 620 nm and presumably therefore, contain very little *meta*-cinnabar). The coating is carried out by dipping the mesh into a suspension of cinnabar produced by boiling a deoxygenated aqueous solution of the powder followed treatment with an ultra-sonic probe. The mesh is removed from the suspension and then dried by hot air. To obtain reproducible results the electrode is stored in an oxygen-free unbuffered 0.1 M sodium nitrate solution (pH 7) for at least 15 h. When such an electrode is placed in an electrolyte solution such as an unbuffered 0.1 M sodium nitrate solution (pH 7) and is connected to a voltmeter (impedance 10^7 – $10^8 \Omega$) with an SCE as reference, illumination of the electrode generates a photo-e.m.f. The light source is a 1.8 kW xenon lamp and the light is filtered by passing it through a 0.28 M copper(II) chloride solution maintained at 5°C. This filter solution has maximal transparency at 515 nm and has a half-band width of 90 nm. The direction of the e.m.f. and plot of the photo e.m.f. versus time (Fig. 1) are all typical of the behaviour of an n-type semiconductor. The photo-e.m.f. is somewhat dependent on the history of the sample but usually falls in the range of -150 to -300 mV. When the cinnabar electrode is connected to a platinum counter electrode and a potential of 0 V maintained between the two by means of a potentiostat and a SCE reference, illumination causes a current to flow (Fig. 2). As expected, the photocurrent increases as the anodic bias is increased. From a determination of the biasing voltage at which zero current flows, the flat band potential of these electrodes was determined as ~ -0.25 V versus SCE at pH 7. This value varies with pH according to the Nernst equation (that is, ~ -60 mV per pH unit). When inert electrolytes such as sodium nitrate, are used, irradiation of such electrodes or suspension of mercury(II) sulphide does not lead to any solubilisation of mercury (as detected by conventional atomic absorption spectroscopy where the lowest reliable

detection of mercury is $7.5 \mu\text{g ml}^{-1}$). We conclude therefore, that the photocurrents are photoelectrolytic currents.

Anodic oxidation could occur on illumination:

One mercury atom should be solubilised per two electrons passed anodically. Stability of HgS was confirmed by passage of enough positive photocurrent to yield a theoretical mercury concentration of $62 \mu\text{g ml}^{-1}$ in the electrolyte: atomic absorption analysis showed that within the detection limit, no mercury solubilisation by anodic oxidation occurs.

Solubilisation of mercury does, however, occur when the electrolyte contains easily oxidisable ions, such as iodide. With these ions, high currents are produced and the red cinnabar changes colour and becomes brownish-black. Preliminary studies have shown that mercury(II) sulphide undergoes a photochemical reaction with iodide and other reducing ions, but as yet the products have not been identified. However, when the darkened electrodes are removed from the electrolyte, washed well with distilled water and then used in an inert electrolyte, no further solubilisation of mercury occurs. Blackening of electrodes by this procedure enables one to prepare electrodes which give significantly higher currents at zero bias ($\sim +15 \mu\text{A}$) than the untreated cinnabar electrodes (see Fig. 2). A bonus is that the darkening extends the spectral response. The nature of the material responsible for the dark colour is uncertain, although X-ray powder photographs and optoacoustic spectra suggest that some of the colour is due to presence of *meta*-cinnabar.

Electrodes which deliver high currents at zero bias are also effective in photo-assisting the electrolysis of water. Thus at pH 12, using degassed sodium nitrate or chloride as electrolyte and a bias of $> +0.2$ V (versus SCE) leads to gas evolution at the platinum counter electrode and gas bubbles on the semiconductor surface can often also be seen.

An auroral effect on the fair weather electric field

EVIDENCE is presented here for coupling between the upper and lower atmosphere by electrical means related to aurorae. Electric field data obtained with rocket-launched parachute-borne probes are shown to be consistent with the hypothesis that aurorally-produced radiation can short out vertical electric field 'cells' in the mesosphere, with corresponding effects on the lower atmosphere electric field.

Effects of solar sunspot-related activity on the lower atmosphere electric field occur too frequently to be explained by direct modulation of the 'classical' global electrical circuit¹, which requires large variations in galactic cosmic-ray flux or rare solar cosmic-ray events which penetrate to the lower stratosphere². Available data indicate responses of the lower atmosphere field to much smaller and more frequent solar and geomagnetic disturbances². Israëli¹ reported observations of the direct effects of aurorae on the surface field by early investigators, and more recent observations of such effects, including balloon measurements, are cited in refs 2 and 3.

One mechanism which may explain some such observations involves the existence in the mesosphere of a large vertical electric field, with a total potential of the order of 100 kV.

Fig. 1 Electric field antenna configuration.

Where this mesospheric field is shorted by ionisation produced by radiation, then this potential may be added to the lower atmosphere potential (~ 300 kV), producing an increase or decrease depending on the direction of the mesospheric field. Large mesospheric fields were first observed in the USSR⁴. Sceptical of this result, we concluded that such fields should have appeared as base-line shifts in previously obtained conductivity measurements using parachute-borne electrical conductivity probes. On checking old data we found evidence of such base-line shifts in several cases⁵, with the largest electric field effect

Fig. 2 The variation of antenna potential with altitude: $\square$, quiet, 22 March 1978 06.52 UT; $\triangle$, disturbed, 27 March 1978 10.26 UT.

appearing in a measurement made in Chilca, Peru, near the magnetic equator. (This may indicate that the fields are generated primarily at low latitudes.) In operation Aurorozone I, aimed at measuring the atmospheric effects of aurorae at Poker Flat Research Range near Fairbanks, Alaska, in September 1976, it was observed that a baseline shift indicating a large electric field was present only during quiet conditions, vanishing during disturbed periods of auroral activity (J. D. Mitchell, personal communication), presumably due to enhanced electrical conductivity. This led to the hypothesis that observed lower atmosphere effects were due to the shorting out of a permanent electrical field cell in the mesosphere, with the associated potential appearing in the lower atmosphere circuit⁶. The existence of such large mesospheric fields may be related to aerosol layers, which make the atmospheric ionisation relatively immobile⁷.

To investigate this phenomenon further, electric field measurements were conducted at Poker Flat during operation Aurorozone II in March 1978. The instruments used 1-m metallic antennas above parachute-suspended payloads, as shown in Fig. 1. Teflon insulation was used to connect the antenna to an electrometer follower (Intersil ICH 8500A). The payload section included telemetry, and also X-ray detectors and a Gerdsen condenser for charged particle measurements (provided by other experimenters). This inherently asymmetric system is capable of measuring relative electric fields at night, when photo-emission from surfaces is unimportant.

Figure 2 shows data obtained from two such launches on Super Arcas rockets. The data, in potential difference between

the antenna and payload (accurate to ± 0.3 V), are approximately the same as the downwards electric field in V m^{-1} , the effective length of the dipole being of the order of 1 m. The data show the field during a very quiet period (22 March, 06.25 UT) and during a disturbed condition (27 March, 10.26 UT) which occurred following the onset of a geomagnetically disturbed period when the Poker Flat riometer indicated over 5 dB of enhanced galactic noise absorption, with extensive visible aurora. There was no reported thunderstorm activity or precipitation (rain or snow) in Alaska during these periods (H. Cole, personal communication).

The quiet data indicate the normal fair weather pattern at lower altitudes, but show an enhancement at high altitudes. The rocket performed less well than expected, so that the peak implied by the highest altitude data points was not attained. The disturbed data indicate a small field at high altitudes, but a substantially higher field at lower altitudes, with some evidence of ragged structure. If the ionosphere is nearly equipotential at a higher altitude, say 100 km, then shorting the mesospheric part of the circuit would be expected to produce a correspondingly altered field in the lower atmosphere, as is observed.

This effect could penetrate to a lower latitude as the amount of radiation necessary to short the mesospheric field may be relatively small. Beyond this the effect would decrease towards lower latitudes as determined by mapping of the field. A more complete global description of the electrical response of the atmosphere to geomagnetic disturbances would require that future auroral zone 'campaigns' be supplemented by measurements at various latitudes. Because of the inferred importance of mesospheric fields to the complete global circuit this would require rocket measurements supplemented by balloon and surface measurements. The most reasonable way of acquiring mesospheric data would seem to be using low cost meteorological rockets as are widely used for wind and temperature measurements, utilising electric field and charged particle sensors deployed on parachutes.

Note that the coupling mechanism suggested above is not necessarily the only one of importance. Direct modulation of the lower atmosphere field has been demonstrated in connection with large solar cosmic ray events⁸. Magnetospheric and ionospheric fields have been shown to map to low altitudes⁹. Rapid responses of the surface field to auroral events^{3,10} may be induced by aurorally produced charge separation.

We thank J. R. Barcus, R. A. Goldberg, J. D. Mitchell and J. J. Olivero for useful discussions. Assistance with rocket payloads and launch operations was provided by personnel of NASA Wallops Flight Center and Poker Flat Research Range of the University of Alaska. D. F. Young assisted with calculations. This work was supported by NASA grant NSG-6004.

Note added in proof: Combining Gerdien condenser conductivity data (J. D. Mitchell, personal communication) with the electric field measurements shows that vertical current density increases rapidly above 30 km in both the quiet and disturbed cases. This seems to indicate that currents with density much higher than the 'fair weather' current circulate in the upper stratosphere and mesosphere, which may explain the nature of the effect described above.

Geomagnetic activity and the high latitude magnetic field of the Sun

SMITH *et al.*¹ using Pioneer 11 in 1976 did not observe any sector structure at the heliographic latitude of about $+16^\circ$. At this latitude the field polarity was consistently directed away from the Sun. Its direction was in accord with the direction of the high-latitude magnetic field near the north pole of the Sun. This result, as well as indirect data²⁻⁴, shows that the high latitude solar field extends far into interplanetary space. The evidence for this is shown by the analysis of the yearly *aa* indices^{5,6} between 1868 and 1976. We find intensification of geomagnetic disturbances during those 11 yr periods when the extended solar magnetic field polarity in the northern hemisphere is away from the Sun.

From measurements by the Mount Wilson^{7,8}, Cambridge⁹ and Crimea¹⁰ magnetographs one finds that the general magnetic field of the Sun varies with a period of ~ 22 yr. Then assuming the first year of the 11-yr cycle and the even numbered years as the beginning of each oscillation and taking the 22-yr Hall cycle period as the unit, one finds that the high latitude field of the Sun is maximum near the phase 0.5. During this interval the field vector is in the same direction as the vector of the angular velocity of the solar rotation, that is, the magnetic field polarity is away from the photosphere in the northern hemisphere. During the interval near phase 1.0, the absolute field value attains a maximum again but its polarity near the poles reverses. The high latitude field approaches zero and reverses near the 0.25 and 0.75 phases, in the neighbourhood of the 11-year cycle maxima.

Fig. 1 The relationship of the yearly *aa* indices of geomagnetic activity with Wolf number (*W*). The lines for $W < 27$ are the approximations from the text, for $W > 60$ the *aa* values are calculated for intervals of *W*. The errors bars are shown.

The Earth migrates at 7°S – 7°N heliographic latitude throughout the year. So the Earth crosses the current sheet, which is almost parallel to the solar equatorial plane and separates the two hemispheres of opposed field polarity. Taking into account Earth's migration and the time variation of the inclination of the geomagnetic dipole, as derived in ref. 11, we find that the projection B_s of the interplanetary magnetic field (IMF) in the direction of the geomagnetic dipole is large enough to have some geomagnetic effect. Near phase 0.5 this component B_s is parallel to the geomagnetic dipole (antiparallel to the geomagnetic field at the magnetopause) and one may expect a reconnection¹² of the IMF and geomagnetic field. This phenomenon increases near phase 0.5 compared with phase 1.0. This must be followed by intensification of geomagnetic activity near the ends of the even cycles in comparison with ends of the odd cycles.

The variation of geomagnetic activity near solar cycle minima has been described elsewhere¹³. The geomagnetic activity index¹⁴ M used for the interval 1884–1967 was based on a regression of M with the Curie indices, and is not homogeneous throughout the whole hundred year interval. Therefore quantitatively comparing the mean M values in periods with different levels of solar activity is not reliable. The difference in mean Curie values in even and odd solar cycles has also been noted by Russell¹⁵.

The aa index introduced by Mayaud^{5,6} is a better index for long-term studies. Mayaud defined the aa index as the average of 3-h K indices converted to the amplitude of the field at two antipodal observatories. The Greenwich and Melbourne Observatories are roughly antipodal and have been gathering data since 1868. Comparing the aa indices with the planetary a_m indices shows¹⁶ that the correlation coefficient between the mean monthly and the mean annual values attains 0.994 and 0.998, respectively. Thus the aa index obtained from the magnetograms of two antipodal observatories gives a good picture of the mean monthly planetary geomagnetic activity.

For years of low solar activity ($W < 27$), the comparison of mean annual aa indices with Zürich Wolf number (W) for 1868–1975 (refs 17, 18) yielded the following linear approximations:

$$aa = (0.31 \pm 0.08)W + (6.98 \pm 1.12) \text{ nT}$$

$$aa = (0.25 \pm 0.11)W + (12.7 \pm 1.11) \text{ nT}$$

for the ends of the 11-yr cycles with odd and even numbers, respectively. The correlation coefficients between aa and W are 0.88 ± 0.06 and 0.42 ± 0.25 for odd and even minima respectively. So, the geomagnetic activity can be seen to be higher near phase 0.5 than near phase 1.0. When the Wolf Numbers vanishes ($W \rightarrow 0$) the aa index for the even cycles remains almost double that for the odd cycles. The dependence of aa on W for the sunspot minimum, together with the aa index averaged over intervals of W at sunspot maxima are shown in Fig. 1.

Fig. 2 The variations of the $\overline{aa}$ indices for the maxima ($\bar{W} = 100$) and the ends of the solar 11-yr cycles ($\bar{W} = 10$).

For the years near the extrema of 11-yr cycles the averaged aa and $\bar{W}$ value are used. For maxima we used the data of the three years interval, the year of maximum W and two neighbouring years, in the cycles nos 15 and 16 the fourth year with a large W was also added. For the minima data with average annual values of $W < 27$ and $aa < 20$ were used. The year 1976 is not suitable for this criterion but as it was the minimum of the solar cycle it was taken as being characteristic of the unusual cycle no. 20. For the end of cycle no. 15 we did not use the 1921 and 1922 data as

W (for 1921) and aa (for 1922) were close to the chosen limiting line. The insertion of these years gives $\overline{aa} = 14.0$ and $\bar{W} = 15.7$ for the 1921–1924 interval. The reduction to $\bar{W} = 10$ gives $\overline{aa} = 12.2$, but that does not change the relationship between geomagnetic disturbance and even polarity of a cycle as shown in Fig. 2.

Table 1 Variation of Wolf numbers with annual aa indices

No. of solar cycle (N)	Maxima			Minima		
	Years	$\overline{aa}$	$\bar{W}$	Years	$\overline{aa}$	$\bar{W}$
11	1870–1872	22.5	117.3	1875–1879	8.8	10.0
12	1882–1884	18.3	62.3	1887–1890	13.8	8.3
13	1892–1894	20.7	78.6	1897–1903	10.6	15.2
14	1905–1907	14.6	59.8	1910–1914	12.4	7.8
15	1916–1919	20.6	76.3	1923–1924	10.2	11.2
16	1926–1929	18.4	68.9	1931–1934	16.4	11.7
17	1937–1939	21.9	104.3	1944–1945	17.0	21.3
18	1947–1949	23.0	141.0	1954	17.3	4.4
19	1957–1959	29.4	177.9	1964–1965	15.6	12.6
20	1968–1970	21.6	105.4	1976	23.8	12.6

The $\overline{aa}$ and $\bar{W}$ values for the cycles from no. 11 to no. 20 are given in Table 1. This shows at sunspot minima, despite the differences in $\bar{W}$, the $\overline{aa}$ indices are greater at the ends of the even cycles than at the ends of the neighbouring odd cycles. At sunspot maxima one can see only the 90-yr variations of $\bar{W}$ with essentially no differences between even and odd cycles.

Using the relationships between aa and W (Fig. 1) the aa indices were reduced to values for $\bar{W} = 10$ and $\bar{W} = 100$, at the minima and maxima of solar cycles respectively. These reduced aa values are shown in Fig. 2. The large differences in aa values seen at sunspot minima in passing from odd to even cycles are absent for sunspot maxima. The difference between the geomagnetic activity during the even and odd minima for cycles 11–20 is given by the ratio $\overline{aa}_{2k}/\overline{aa}_{2k-1} = 1.53 \pm 0.05$ (where $N = 2k$ and $2k - 1 = \text{No. of the cycle}$).

The 11-yr and 22-yr mean values of the aa index are given by Russell¹⁹ for the period 1872–1967. However, he used mean values of the cycles, and did not normalise for the difference in the levels of solar activity as measured by sunspot number. Therefore an enhancement of the aa index at the ends of even cycles as compared with the odd cycles was not confirmed.

Our investigation shows evidence of the existence of an extended solar magnetic field and its variation within a 22-yr period. The physics of this phenomenon is as follows. The temperature (and the density) of the solar corona is lower at high latitude near the sunspot minima. The weakened solar wind in this region does not affect the magnetic field. Thus the magnetic field in the vicinity of the Sun must be nearly a dipole, particularly at high latitudes. This is consistent with the structure of a sunspot minimum solar corona. Near the solar equatorial plane the kinetic and thermal energies become more than the energy of dipole magnetic field, that is $\beta = (1/2\rho U^2 + 3N_e kT)/B^2/8\pi \approx 1$ at a distance of $9R_\odot$. Consequently, the solar wind attracts the field lines near the solar equator plane at a distance of $\sim 9R_\odot$. Thus the field has one polarity in the hemisphere north of the solar equatorial plane and the opposite polarity in the hemisphere south of the equatorial plane. Assuming that the total flux for the entire polar region reaches 3×10^{21} Mx and that the magnetic field B is proportional to r^{-3} for $r < 9R_\odot$ and B is proportional to r^{-2} for $r > 9R_\odot$, we obtain $B \sim 1$ nT near the Earth's orbit.

We thank Professor J. S. Shklovsky for constructive comments.

A radiocarbon date from Lake Bogoria, Kenya Rift Valley

RADIOMETRIC dates from faunal remains deposited in lacustrine and fluvio-lacustrine sediments at numerous locations in and around the lakes of the Kenya Rift Valley confirm a period of extended lake development related to a wetter climatic phase ~10,000 yr ago¹⁻⁷. Thereafter, a drier climatic regime has prevailed and the lakes have contracted, although fluctuating in rapid response to sequences of wetter or drier years. Lake Bogoria (Hannington) is the last of the Kenya Rift Valley lakes to yield a radiocarbon date for this early Holocene high stand. Although a general synchronism of maximal lake development has emerged, as we report here, there is considerable variation in the dates obtained from each lake basin (Fig. 1).

Saline-alkaline Lake Bogoria lies in a fault-controlled trough just north of the Equator⁸⁻⁹, extends north-south for 17 km, varies in width from 500 to 3,500 m (Fig. 2), and has a maximum depth of ~9 m¹⁰. It is sharply delimited by alkaline lavas of Miocene to Pleistocene age⁸⁻⁹, except on its northern margin, where the 1-10 km wide, swamp-covered, Lobo Plain leads for 20 km north across a low watershed to fresh water Lake Baringo. Short ephemeral streams and the semi-permanent Sandai River drain into Lake Bogoria, which also receives water from three groups of hot springs and small geysers. Lake Bogoria has no proven outlet, although underground seepage to the north is likely⁸. Fluvio-lacustrine sediments fringe the lake margins, but are seldom more than a few tens of metres wide except at the northern end. A grey, stromatolitic limestone that coats *in situ* bedrock and clastic sediments up to ~11 m above present lake level, and fossiliferous silts, are the principal evidence for a formerly more extended lake. Excepting algae, no organic life is known to exist in Lake Bogoria today, although crocodiles and hippopotami were photographed swimming in

the lake in 1927 (ref. 11). Mollusc shells, crocodile, hippopotamus and fish bones, and diatoms in fluvio-lacustrine sediments up to 5 m above present lake level, indicate a formerly richer fauna/flora and suggest a fresher water environment. Today the pH of Lake Bogoria exceeds 10.8 and the Na⁺ concentration reaches 28,400 p.p.m.^{8,12}.

A 250 g sample of *Melanoides tuberculata* was collected from the lower part of a 2 m thick fluvio-lacustrine unit of feldspathic silts with pebble bands, the base of which varies from 2.95 to 3.10 m above the July-August 1976 level of Lake Bogoria (Fig. 2). The state of preservation of the shells was good and they were believed to be *in situ* rather than derived. After dissolving and discarding the outer layers of the shells (~20%), dates of 10,560 ± 170 yr BP and 10,320 ± 150 yr BP (Birm-883) were obtained for the inner and middle fractions respectively. In each case the final figure is a conventional radiocarbon date, calculated using a half life of 5,570 ± 30 yr and has been normalised to account for isotopic fractionation effects with respect to a -25‰ enrichment on the PDB limestone scale. The two results are scarcely significantly different and there is therefore little likelihood of isotopic replacement having taken place after deposition (R. E. G. Williams, personal communication).

Fig. 1 Lakes of the Kenya Rift Valley. Radiocarbon dates (yr BP) of maximum Holocene extension of the lakes are indicated to the west (left) of the individual lakes or locations.

The possibility of a greater Lake Baringo that may at times have included Lake Bogoria has been discussed frequently^{8-9,13-17}. Fluvio-lacustrine Lobo Silts, which form the bulk of the sedimentary mass of the Lobo Plain have traditionally been considered of Holocene age⁸. Bogoria Silts, which are deposits of a later transgression, have recently been recognised overlying Lobo Silts in the northern Bogoria basin¹⁷. They may correlate with the early Holocene Eokwob Formation^{16,18,19} of the northern Baringo Basin, thus making the Lobo Silts of late Pleistocene age¹⁷. Whichever interpretation is correct, it has been unclear whether only one early Holocene lake existed ('Kobwob Lake') or whether the two lakes rose and fell independently of each other^{9,13,16,17}.

Radiocarbon dates for samples of *M. tuberculata* collected from a series of strandlines up to 15.85 m above the 1973 level

of Lake Baringo provide evidence of a more extended lake between 10,000 and 14,000 yr BP (Birm-541, 542, 544, 545) (Fig. 2). Shells from the highest strandline on the western margin of Lake Baringo yielded dates of $13,670 \pm 320$ yr BP (inner fraction) and $13,850 \pm 430$ yr BP (middle fraction) (Birm-542). In contrast, dates of $11,870 \pm 310$ yr BP (inner fraction) and $10,860 \pm 280$ yr BP (middle fraction) were obtained for shells from a strandline at the same height (W. W. Bishop, personal communication) immediately north of the Bogoria/Baringo watershed (Birm-541). There is no evidence of Holocene faulting in the area; and unless a lake which attained the same

maximum at different times or fluctuated around that maximum for $\sim 2,000$ yr is proposed, one of the dates seems to be spurious. The Birm-544 and 545 dates were obtained for shell samples from lacustrine sediments in lower locations, 15.54 m and 10.06 m respectively above the level of Lake Baringo.

The Birmingham dates for the Baringo and Bogoria basins are generally $\sim 1,000$ yr older than those obtained for the other Kenya Rift Valley lakes (Fig. 1). Isotopic replacement seems to have occurred in the samples from Lake Baringo, resulting in discrepancies between middle and inner shell fractions (W. W. Bishop, personal communication), and in both basins, there is the possibility of hard water effects due to ancient CO_2 derived from hot spring waters and some of the lake water bicarbonate could have been derived from alkaline lavas.

Complete correlation between the two lakes remains impossible because of a lack of accurate inter-basin altimetric evidence and conflict in the presently available heights of key locations in the two basins. The most recently available heights of the surface of Lake Bogoria and Lake Baringo are 989.5 m (ref. 10) and 967.0 m (ref. 13) respectively. Both lakes are subject to seasonal and longer-term fluctuations of several metres. The height of the relatively inaccessible watershed between the lakes is of critical importance and we suggest that it may lie at ~ 10 m above the 1976 level of Lake Bogoria, which is intermediate to two other recent estimates^{13,17}. Holocene tectonic activity is not considered likely although a northward tilt of the basin floor may have occurred^{6,15}. Whilst not resolving the problem of the existence of a single combined Kokwob Lake, the new date suggests high stands of both lakes at a period $\sim 10,500$ yr BP and makes a single large lake, or an extension of the intervening swamp a considered possibility. The relationship of the $+11$ m limestone to the early Holocene lake levels remains uncertain.

The range of dates for maximum extension of the lakes in the Kenya Rift Valley may reflect differences in the topographical and hydrological properties of each basin, as well as difficulties in comparing directly radiocarbon dates from different laboratories. In addition, the approximately linear north to south decrease in the dates (Fig. 1) may be partly explained by early Holocene regional climatic variations between 2°N and 2°S .

This research was financed by the NERC, the University of Edinburgh and the 20th International Geographical Congress Research Fund. The University of Birmingham provided the radiocarbon measurements. We thank the late Professor W. W. Bishop, Professor W. R. Farrand, Dr W. J. French, R. B. Owen, Miss F. A. Street, R. E. G. Williams and Mrs G. M. Young for all their assistance.

Phytoplankton growth and cyclonic eddies

AROUND the British Isles thermal fronts¹ develop during the summer months between cold, well mixed waters that are relatively rich in inorganic nutrients and warm, well stratified waters that are nutrient depleted². The surface standing crop of phytoplankton is generally high in the marginally stratified frontal zone, particularly where the water is deep (for example, off Ushant and around Orkney and Shetland)², although these surface waters are generally low in inorganic nutrients. To

Table 1 Surface (2m) hydrographic data and phytoplankton cell counts for stations representative of stratified, frontal and mixed waters (the station positions are shown in Figs 1 and 4a)

understand the growth of these frontal blooms, therefore, the scales³ of non-tidal motion that determine the exchange of chemical and biological properties in frontal regions need to be identified. Although the frontal boundaries are almost in geostrophic balance, they are unstable and are characterised by cyclonic eddies with a spatial extent of 20–40 km which can persist for a few days⁴. These eddies probably have an important influence on phytoplankton growth through the transfer of nutrients as well as phytoplankton across the frontal zone. Furthermore, as the division time of the plant cells is relatively short (~1 d), growth of the population may actually occur in the eddy transfer process. In this letter a series of observations on the Ushant frontal system, planned to investigate this problem, are described.

An infrared satellite image (Fig. 1), taken on 14 July 1978, shows a series of eddies in the frontal region between the cold, well mixed waters close to the coast of France and the warm, well stratified waters of the Celtic Sea [such baroclinic eddies are comparable with the well-known atmospheric cyclones that occur in the westerlies on a one-hundred times larger scale]. The area defined by the inset was chosen for detailed study (Fig. 2) after a preliminary hydrographic survey (13–14 July) had indicated that eddy formation was most likely in this region and, accordingly, a current meter mooring was laid at station 038.

Fig. 1 Infrared satellite image of the southwestern approaches to the English Channel, taken at 10.40 GMT on 14 July 1978. Mooring 038 was located at 48°42' 75" N, 05°43' 85" W (see Fig. 2a). The inset outlines the area shown in Figs 2 and 4, and stations W and Z are referred to in Table 1.

These current records did not reveal eddy motions (Fig. 3a) but allow tidal corrections to be made to plots of the ship's track.

The surface distributions of temperature, salinity and chlorophyll *a* all reflect the cyclonic eddy structure seen in the infrared image (Fig. 2) and, as expected, the temperature profiles (Fig. 3b) showed that the cold arm of the eddy was less stratified than the adjacent warmer water. This detailed survey

Fig. 2 *a, b, c*, Surface (2m) distributions of temperature (°C), salinity (‰) and chlorophyll *a* (mg m⁻³) between 18.30, 14 July and 03.20 GMT 15 July 1978. *d*, Infrared satellite image, enlarged from Fig. 1. The ship's track, shown in (*b*), was corrected for tidal displacement before contouring the hydrographic data. Expendable bathythermograph (XBT) casts were made at positions A–E (see Fig. 3*b*).

Fig. 3 *a*, Current records at 15m (98m off bottom) from mooring 038 (see Figs 1 and 2). The mooring was laid during neap tides and recovered during spring tides. The crosses mark the midnight and midday time intervals. *b*, XBT records at positions A–E (see Fig. 2*a*). The discrepancies in surface temperature shown here and in Fig. 2*a* are due to differences between 0 and 2m and the inherent smoothing effects of the deck bucket system used for continuous measurements whilst steaming (see ref. 7).

Fig. 4 Surface (2m) cell counts (ml^{-1}) for a, *Gyrodinium aureolum* and b, the diatom species listed in Table 1. (+) indicates <1 cell ml^{-1} . The position of the eddy is marked by the 14.5° and 13.5° temperature contours.

was repeated daily between 17 and 20 July, but over this period the surface temperature structure gradually became more diffuse and no new eddy structures were found, or could be detected subsequently by examination of satellite images. Surface chlorophyll *a* levels remained very variable, with high values (up to 20 mg m^{-3}) associated with horizontal temperature gradients as well as with temperature minima.

The data presented in Fig. 2 give the first confirmation of the suggestion that eddy structures seen on satellite pictures are intrusions of cold, mixed water into warmer, more stratified water. However, the coldest, saltiest region was isolated within the spiral arm of the eddy, suggesting that some of this water may have had a more local origin through upward displacement of the thermocline. The strongest evidence in support of this hypothesis comes from phytoplankton cell counts (Fig. 4) which show that the dominant organism in the cold water patch was *Gyrodinium aureolum* Hulbert, a dinoflagellate characteristic of chlorophyll-rich layers in shallow thermoclines⁵. (Vertical profiles close to the position of the eddy gave sub-surface chlorophyll *a* concentrations and cell counts for *G. aureolum* as high as 200 mg m^{-3} and 10^4 ml^{-1} respectively.) In contrast, diatoms which persist in the well mixed waters throughout the summer⁵ were relatively scarce within this cold water patch.

The distributions of phytoplankton species and inorganic nutrients across the frontal region are summarised in Table 1. It seems that the higher chlorophyll levels in water of frontal properties were due partly to a general increase in the abundance of several diatom and dinoflagellate species and partly to localised patches of *Gyrodinium aureolum* derived from the thermocline. The latter may initiate through a 'seeding' effect the development of widespread blooms of *G. aureolum* that have been observed occasionally in previous summers in the western English Channel⁶. Further experimental studies at sea are now required to establish quantitatively whether mixing of nutrients across frontal regions, due to cyclonic eddies, has a significant effect on annual primary production.

We have been concerned primarily with the influence of eddies on the transfer and growth of phytoplankton in the frontal regions around the British Isles³. The ideas developed here are also important in understanding the cross-frontal transfer and dispersal of other properties, such as heat, radioactive material, hydrocarbons and industrial wastes which are now causing much public concern in our heavily exploited shelf seas.

Flight capability and the pectoral girdle of *Archaeopteryx*

AS the earliest birds known, the late Jurassic specimens of *Archaeopteryx* have been the object of great speculative interest. Ostrom^{1–3} has argued that *Archaeopteryx* was a terrestrial, cursorial predator that represents a preflight stage in the origin of birds in which the forelimbs were used as nets to trap insects. So far, this has been challenged mainly on the grounds that such activity would have caused excessive feather wear⁴. The principal evidence for regarding *Archaeopteryx* as flightless, or at best an inept non-flapping glider, has come from interpretations of the structure of the pectoral girdle. The absence of an ossified sternum for attachment of flight muscles has long been cited. More recently, it has been argued that the structure of the coracoid of *Archaeopteryx* would not have permitted the supracoracoideus muscle to function as a wing elevator^{2,5}. Because the asymmetrical remiges of *Archaeopteryx* prove that

the wing had an aerodynamic function⁶, we now hope to show that neither of the preceding points precludes a capacity for powered flight in *Archaeopteryx*.
